Chapter 16. Acid-Base Equilibria and Solubility Equilibria

What we will learn:

• Homogeneous and heterogeneous solution equilibria
• Common ion effect
• Buffer solutions
• Acid-base titrations
• Acid-base indicators
• Solubility equilibria
• Separation of ions by fractional precipitation
• Common ion effect and solubility
• pH and solubility
• Complex ion equilibria and solubility
Homogeneous solution equilibria

Solution equilibrium related to reactions in which all components are in the same phase

Heterogeneous solution equilibria

Solution equilibrium related to reactions in which the components are in more than one phase
The common ion effect

*The shift in equilibrium caused by the addition of a compound having an ion in common with the dissolved substance*

**Example**

The solution of two different compounds having a common ion

\[
CH_3COONa(s) \rightarrow CH_3COO^-(aq) + Na^+(aq)
\]

\[
CH_3COOH(aq) \rightleftharpoons CH_3COO^-(aq) + H^+(aq)
\]

Adding CH₃COONa to a solution of CH₃COOH increases a concentration of CH₃COO⁻, which (Le Chatelier principle) decreases a concentration of H⁺
HA(aq) + H₂O(l) ⇌ H₃O⁺(aq) + A⁻(aq)

HA(aq) ⇌ H⁺(aq) + A⁻(aq)

Kᵦ = [H⁺][A⁻]/[HA]

[H⁺] = Kᵦ[HA]/[A⁻]

-log [H⁺] = -log Kᵦ - log ([HA] / [A⁻])

-log [H⁺] = -log Kᵦ + log ([A⁻] / [HA])

pH = pKᵦ + log([A⁻] / [HA])

pKᵦ = -log Kᵦ

pH = pKᵦ + log([base] / [acid])
Problem

Calculate the pH of a 0.2 \( M \) \( \text{CH}_3\text{COOH} \) solution. What is the pH of a solution containing both 0.2 \( M \) \( \text{CH}_3\text{COOH} \) and 0.3 \( M \) \( \text{CH}_3\text{COONa} \). The \( K_a \) of \( \text{CH}_3\text{COOH} \) is 1.8 x 10^{-5}.

\[
\text{CH}_3\text{COOH}(aq) \rightleftharpoons H^+(aq) + \text{CH}_3\text{COO}^-(aq)
\]

<table>
<thead>
<tr>

\[
K_a = \frac{[H^+][\text{CH}_3\text{COO}^-]}{[\text{CH}_3\text{COOH}]} = 1.8 \times 10^{-5}
\]

\[
1.8 \times 10^{-5} = x^2 / (0.2 - x)
\]

\[
x = 1.9 \times 10^{-3} \text{ M}
\]

\[
pH = -\log(1.9 \times 10^{-3}) = 2.27
\]
\[ \text{CH}_3\text{COONa}(aq) \rightarrow \text{Na}^+(aq) + \text{CH}_3\text{COO}^-(aq) \]

Initial (M) 0.3 0.0 0.0
Change (M) -0.3 +0.3 +0.3

Final (M) 0 0.3 0.3

The initial concentration of the base will change

\[ \text{CH}_3\text{COOH}(aq) \rightleftharpoons \text{H}^+(aq) + \text{CH}_3\text{COO}^-(aq) \]

Initial (M) 0.2 0 0.3
Change (M) -x +x +x

Equilibrium (M) 0.2 - x x 0.3 + x

\[ K_a = \frac{[H^+] [\text{CH}_3\text{COO}^-]}{[\text{CH}_3\text{COOH}]} \]

\[ 1.8 \times 10^{-5} = (x) (0.3 + x) / (0.2 - x) \]
\[ x = 1.2 \times 10^{-5} \, M \]

\[ \text{pH} = -\log[H^+] \]

\[ = -\log(1.2 \times 10^{-5}) = 4.92 \]
Buffer solutions

The solution of a weak acid (or a weak base) and its salt

The buffer solution has the ability to resist changes in pH upon the addition of small amount of an acid or a base

Example

A solution of acetic acid (CH$_3$COOH) and sodium acetate (CH$_3$COONa)

\[
CH_3COONa(s) \rightarrow CH_3COO^-(aq) + Na^+(aq)
\]
If an acid is added, the $H^+$ will be consumed according to the reaction

$$CH_3COO^-(aq) + H^+(aq) \rightleftharpoons CH_3COOH(aq)$$

If a base is added, the $OH^-$ will be consumed according to the reaction

$$CH_3COOH(aq) + OH^-(aq) \rightleftharpoons CH_3COO^-(aq) + H_2O(l)$$

**Problem**

Calculate the pH of a buffer system containing 1.0 $M$ CH$_3$COOH and 1.0 $M$ CH$_3$COONa. What is the pH of the buffer system after the addition of 0.10 mole of gaseous HCl to 1.0 L of the solution.
\[ \text{CH}_3\text{COOH}(aq) \rightleftharpoons H^+(aq) + \text{CH}_3\text{COO}^-(aq) \]

<table>
<thead>
<tr>
<th>Initial (M)</th>
<th>1.0</th>
<th>0</th>
<th>1.0</th>
</tr>
</thead>
<tbody>
<tr>

<td>x</td>
<td>1.0 + x</td>
</tr>
</tbody>
</table>

\[ K_a = \frac{[H^+] [\text{CH}_3\text{COO}^-]}{[\text{CH}_3\text{COOH}]} \]

\[ 1.8 \times 10^{-5} = (x) (1.0 + x) / (1.0 - x) \]

\[ x = 1.8 \times 10^{-5} \text{ M} \]

\[ \text{pH} = -\log(1.8 \times 10^{-5}) = 4.74 \]

When the HCl is added, the initial concentrations are

<table>
<thead>
<tr>
<th>Initial (M)</th>
<th>\text{HCl}(aq)</th>
<th>\rightarrow</th>
<th>\text{H}^+(aq)</th>
<th>+</th>
<th>\text{Cl}^-(aq)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Change (M)</td>
<td>-0.1</td>
<td></td>
<td>+0.1</td>
<td></td>
<td>+0.1</td>
</tr>
<tr>
<td>Final (M)</td>
<td>0</td>
<td>0.1</td>
<td>0.1</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
The $H^+$ ions provided by the strong HCl react completely with the $CH_3COO^-$ base. At this point it is more convenient to work with the number of moles rather than molarity. The change in volume will change the molarity but not the number of moles.

\[
CH_3COO^-(aq) + H^+(aq) \rightarrow CH_3COOH(aq)
\]

<table>
<thead>
<tr>
<th>Initial (mol)</th>
<th>1.0</th>
<th>0.1</th>
<th>1.0</th>
</tr>
</thead>
<tbody>

<td>-0.1</td>
<td>+0.1</td>
</tr>
<tr>
<td>Final (mol)</td>
<td>0.90</td>
<td>0</td>
<td>1.1</td>
</tr>
</tbody>
</table>

Finally, we calculate the pH of the buffer after neutralization, taking the final concentrations of the species.

\[
CH_3COOH(aq) \leftrightharpoons H^+(aq) + CH_3COO^-(aq)
\]

<table>
<thead>
<tr>
<th>Initial (M)</th>
<th>1.1</th>
<th>0</th>
<th>0.9</th>
</tr>
</thead>
<tbody>
<tr>
<td>Change (M)</td>
<td>-x</td>
<td>+x</td>
<td>+x</td>
</tr>
<tr>
<td>Equilibrium (M)</td>
<td>1.1 - x</td>
<td>x</td>
<td>0.9 + x</td>
</tr>
</tbody>
</table>
\[ K_a = \frac{[H^+] [CH_3COO^-]}{[CH_3COOH]} \]

\[ 1.8 \times 10^{-5} = (x) (0.9 + x) / (1.1 - x) \]

\[ x = 2.2 \times 10^{-5} \text{ M} \]

\[ \text{pH} = -\log(2.2 \times 10^{-5}) = 4.66 \]
Making a buffer solution with specific pH

The molar concentrations of the acid and its conjugate base are approximately equal

\[ pH = pK_a + \log([\text{base}] / [\text{acid}]) \]

\[ \log([\text{base}] / [\text{acid}]) \approx 0 \]

\[ pH \approx pK_a \]

Example

Prepare a phosphate buffer solution with a pH of about 7

Solution

The concentration of the acid should be roughly equal to the concentration of its conjugate base
\[
\log \left( \frac{[\text{base}]}{[\text{acid}]} \right) = 0
\]

\[
[\text{base}] / [\text{acid}] = 1
\]

The phosphoric acid is a triprotic acid

\[
\begin{align*}
H_3PO_4(aq) & \rightleftharpoons H^+(aq) + H_2PO_4^-(aq) & K_{a1} = 7.5 \times 10^{-3} & \text{pK}_{a1} = 2.12 \\
H_2PO_4^-(aq) & \rightleftharpoons H^+(aq) + HPO_4^{2-}(aq) & K_{a2} = 6.2 \times 10^{-8} & \text{pK}_{a2} = 7.21 \\
HPO_4^{2-}(aq) & \rightleftharpoons H^+(aq) + PO_4^{3-}(aq) & K_{a3} = 4.8 \times 10^{-13} & \text{pK}_{a3} = 12.32
\end{align*}
\]

The most suitable of the three buffer systems is \(HPO_4^{2-} / H_2PO_4^-\) because the \(pK_a\) is closest to the desired pH

\[
pH = K_a + \log\left( \frac{[\text{base}]}{[\text{acid}]} \right)
\]

\[
7.40 = 7.21 + \log\left( \frac{[HPO_4^{2-}]}{[H_2PO_4^-]} \right)
\]

\[
\log\left( \frac{[HPO_4^{2-}]}{[H_2PO_4^-]} \right) = 0.19
\]

\[
[\text{HPO}_4^{2-}] / [\text{H}_2\text{PO}_4^-] = 10^{0.19} = 1.5
\]
Therefore we need to prepare a phosphate buffer with a pH of 7.40, by dissolving disodium hydrogen phosphate (Na$_2$HPO$_4$) and sodium dihydrogen phosphate (NaH$_2$PO$_4$) in a mole ratio 1.5/1.0 in water. For example we could dissolve 1.5 moles of Na$_2$HPO$_4$ and 1.0 mole NaH$_2$PO$_4$ in enough water to make up a 1 L solution.

**Acid base titrations**

*Neutralization of an acid by a base, or a base by an acid*

- Titrations with a strong acid and a strong base
- Titrations with a weak acid and a strong base
- Titrations with a strong acid and a weak base
Strong acid and a strong base titrations

Example

\[ \text{NaOH (aq)} + \text{HCl (aq)} \rightarrow \text{NaCl (aq)} + \text{H}_2\text{O (l)} \]

Net ionic charges

\[ \text{H}^+(\text{aq}) + \text{OH}^-(\text{aq}) \rightarrow \text{H}_2\text{O(l)} \]

Calculations of pH at different steps of titrations

1. Addition of 10.0 mL 0.1 \( M \) NaOH to 25.0 mL of 0.1 \( M \) HCl

   Number of moles of NaOH in 10.0 mL

   \[
   10.0 \text{ mL} \times \frac{0.1 \text{ mol NaOH}}{1 \text{ L NaOH}} \times \frac{1 \text{ L}}{1000 \text{ mL}} = 1 \times 10^{-3} \text{ mol}
   \]
Number of moles of HCl originally present in 25.0 mL of solution

\[ 25.0 \text{ mL} \times \frac{0.1 \text{ mol HCl}}{1 \text{ L HCl}} \times \frac{1 \text{ L}}{1000 \text{ mL}} = 2.5 \times 10^{-3} \text{ mol} \]

Amount of HCl left after partial neutralization

\[ (2.5 \times 10^{-3}) - (1.0 \times 10^{-3}) = 1.5 \times 10^{-3} \text{ mol} \]

The concentration of H\(^+\) ions in 35.0 mL of solution

\[ \frac{1.5 \times 10^{-3} \text{ mol HCl}}{35.0 \text{ mL}} \times \frac{1000 \text{ mL}}{1 \text{ L}} = 0.0429 \text{ M HCl} \]

\[ \text{pH} = -\log(0.0429) = 1.37 \]

2. Addition of 25.0 mL of 0.1 M NaOH to 25 mL of 0.1 M HCl

(NaCl does not undergo hydrolysis)

\[ [\text{H}^+] = [\text{OH}^-] = 1.0 \times 10^{-7} \text{ M} \]

\[ \text{pH} = 7.0 \]
3. Addition of 35.0 mL of 0.1 M NaOH to 25.0 mL 0.1 M HCl

\[
35.0 \text{ mL} \times \frac{(0.1 \text{ mol NaOH})}{(1 \text{ L NaOH})} \times \frac{1 \text{ L}}{1000 \text{ mL}} = 3.5 \times 10^{-3}
\]

The number of moles of HCl in 25.0 mL solution is 2.5 \times 10^{-3} mol. After complete neutralization of HCl, the number of moles of NaOH left is

\[
(3.5 \times 10^{-3}) - (2.5 \times 10^{-3}) = 1 \times 10^{-3} \text{ mol}
\]

The concentration of NaOH in 60.0 mL of solution is

\[
\frac{(1 \times 10^{-3} \text{ mol NaCl})}{(60.0 \text{ mL}) \times (1000 \text{ mL})} = 0.0167 \text{ mol NaCl} / \text{L}
\]

\[
[\text{OH}^-] = 0.0167 \text{ M}
\]

pOH = 1.78

pH = 12.22
Weak acid and a strong base titrations

Example

\[ \text{CH}_3\text{COOH (aq)} + \text{NaOH (aq)} \rightarrow \text{CH}_3\text{COONa (aq)} + \text{H}_2\text{O (l)} \]

Simplification

\[ \text{CH}_3\text{COOH (aq)} + \text{OH}^- (aq) \rightarrow \text{CH}_3\text{COO}^- (aq) + \text{H}_2\text{O (l)} \]

Weak acid reacts with water (hydrolysis)

\[ \text{CH}_3\text{COO}^- (aq) + \text{H}_2\text{O (l)} \rightleftharpoons \text{CH}_3\text{COOH (aq)} + \text{OH}^- (aq) \]

Calculate the pH in the titration of 25.0 mL of 0.1 M acetic acid (CH$_3$COOH) by sodium hydroxide (NaOH) after the addition

(a) 10.0 mL of 0.1 M NaOH

(b) 25.0 mL 0.1 M NaOH

(c) 35.0 mL of 0.1 M NaOH
a) Number of moles of NaOH present in 10.0 mL is

\[
10.0 \text{ mL} \times \left(\frac{0.1 \text{ mol NaOH}}{1 \text{ L NaOH soln}}\right) \times \left(\frac{1 \text{ L}}{1000 \text{ mL}}\right) = \\
= 1.0 \times 10^{-3} \text{ mol}
\]

Number of moles of \(\text{CH}_3\text{COOH}\) originally present in 25.0 mL is

\[
25.0 \text{ mL} \times \left(\frac{0.1 \text{ mol } \text{CH}_3\text{COOH}}{1 \text{ L CH}_3\text{COOH soln}}\right) \times \left(\frac{1 \text{ L}}{1000 \text{ mL}}\right) = \\
= 2.5 \times 10^{-3} \text{ mol}
\]
We work with moles because two solutions are mixed and the volume of the final solution increases. The molarity will change however, the number of moles will remain the same.

\[
CH_3COOH(aq) + NaOH(aq) \rightarrow CH_3COONa(aq) + H_2O(l)
\]

<table>
<thead>
<tr>
<th>Initial (mol)</th>
<th>2.5 x 10^{-3}</th>
<th>1.0 x 10^{-3}</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>

<tr>
<td>Final (mol)</td>
<td>1.5 x 10^{-3}</td>
<td>0</td>
<td>1.0 x 10^{-3}</td>
</tr>
</tbody>
</table>

We have a buffer made up of CH\textsubscript{3}COOH and CH\textsubscript{3}COO\textsuperscript{-} (from the salt). We can calculations of the pH solution:

\[
K_a = [H^+] [CH_3COO^-] / [CH_3COOH] = 1.8 \times 10^{-5}
\]

\[
[H^+] = [CH_3COOH] K_a / [CH_3COO^-]
\]

\[
= (1.5 \times 10^{-3}) (1.8 \times 10^{-5}) / (1.0 \times 10^{-3}) = 2.7 \times 10^{-5} \text{ M}
\]

pH = 4.57
b) 25.0 mL of 0.1 \( M \) NaOH reacting with 25.0 mL of 0.1 \( M \) \( CH_3COOH \) corresponds to the equivalence point. At the equivalence point the concentrations of both the base and the acid are zero. The number of moles of NaOH in 25.0 mL of the solution is

\[
25.0 \text{ mL} \times \frac{0.1 \text{ mol NaOH}}{1 \text{ L NaOH soln}} \times \frac{1 \text{ L}}{1000 \text{ mL}} =
\]

\[
= 2.5 \times 10^{-3} \text{ mol}
\]

The changes in number of moles are

\[
CH_3COOH(aq) + NaOH(aq) \rightarrow CH_3COONa(aq) + H_2O(l)
\]

<table>
<thead>
<tr>
<th></th>
<th>Initial (mol)</th>
<th>Change (mol)</th>

Calculations of the pH solution using only the concentration of OH⁻ ions from the final concentration of NaOH

\[
[\text{OH}^-] = \frac{(1.0 \times 10^{-3} \text{ mol})}{(60.0 \text{ mL}) \times (1000 \text{ mL})} / (1 \text{ L})
\]

= \[0.0167 \text{ } M\]

\[\text{pOH} = - \log(0.0167)\]

\[\text{pH} = 12.22\]
Acid base indicators

A substance which changes its color when a titration is at the end point

Example

\[ HIn(aq) \rightleftharpoons H^+(aq) + In^-(aq) \]

\[ K_{in} = \frac{[In^-][H^+]}{[HIn]} \quad \frac{[HIn]}{[In^-]} = \frac{[H^+]}{K_{in}} \]

\[ \frac{[HIn]}{[In^-]} > 10.0 \quad \text{color of acid (HIn)} \]

\[ \frac{[HIn]}{[In^-]} < 0.1 \quad \text{color of base (In^-)} \]

between 0.1 and 10.0 the color is a combination of two colors

Phenolphthalein

In acid solution = colorless
In base solution = pink
pH range = 8.3 - 10
Solubility equilibria

Solubility product

A product of the molar concentration of the constituent ions, each raised to the power of its stoichiometric coefficient in the equilibrium equation

Example

\[ \text{AgCl(s)} \rightleftharpoons \text{Ag}^+(aq) + \text{Cl}^-(aq) \]

The concentration of solid silver chloride (AgCl) is a constant (heterogeneous reaction)

\[ K_{sp} = [\text{Ag}^+] [\text{Cl}^-] \]

\[ \text{MgF}_2(s) \rightleftharpoons \text{Mg}^{2+}(aq) + 2 \text{F}^-(aq) \]

\[ K_{sp} = [\text{Mg}^{2+}] [\text{F}^-]^2 \]
Molar solubility and solubility

**Solubility** - the number of grams of a solute in 1 L of a saturated solution (g/L)

**Molar solubility** - the number of moles of a solute in 1 L of a saturated solution (mol/L)

Example

The solubility of calcium sulfate (CaSO₄) is found to be 0.67 g/L. Calculate the value of $K_{sp}$ for calcium sulfate

$$CaSO_4(s) \rightleftharpoons Ca^{2+}(aq) + SO_4^{2-}(aq)$$

| Initial (M) | 0 | 0 |
| Change (M)  | -s | +s | +s |
| Equilibrium (M) | s | s |
The solubility product

\[
K_{sp} = [Ca^{2+}][SO_{4}^{2-}] = s^2
\]

The number of moles of CaSO₄ dissolved in 1 L of solution

\[
(0.67 \text{ g CaSO}_4) / (1 \text{ L soln}) \times (1 \text{ mol CaSO}_4) / (136.2 \text{ g CaSO}_4) = \\
= 4.9 \times 10^{-3} \text{ mol/L} = s
\]

Calculations of \( K_{sp} \)

\[
K_{sp} = [Ca^{2+}][SO_{4}^{2-}]
\]

\[
= (4.9 \times 10^{-3}) (4.9 \times 10^{-3})
\]

\[
= 2.4 \times 10^{-5}
\]
Separation of ions by fractional precipitation

Removing of one type of ion from solution by precipitation, leaving other ions in solution

Precipitation - to separate a substance in solid form from a solution

Example

Addition of sulfate ions to a solution containing both potasion (K) and barium (Ba) ions causes $\text{BaSO}_4$ to precipitate out

Problem

A solution contains $0.02\ M\ \text{Cl}^-$ ions and $0.02\ M\ \text{Br}^-$ ions. What concentration of $\text{Ag}^+$ is needed to precipitate $\text{AgBr}$ (silver bromide) and $\text{AgCl}$ (silver chloride).
Solution

\[ AgBr(s) \rightleftharpoons Ag^+(aq) + Br^-(aq) \]

The concentration of \( Ag^+ \) must be exceeded to initiate the precipitation of AgBr

\[ K_{sp} = [Ag^+] [Br^-] = 7.7 \times 10^{-13} \]

\[ [Ag^+] = K_{sp} / [Br] \]

\[ = (7.7 \times 10^{-13}) / (0.02) \]

\[ = 3.9 \times 10^{-11} \text{ M} \]

Thus \( [Ag^+] > 3.9 \times 10^{-11} \text{ M} \) is required to start the precipitation of AgBr
Similarly, the solubility equilibrium of AgCl is

\[ \text{AgCl(s)} \rightleftharpoons \text{Ag}^+(aq) + \text{Cl}^-(aq) \]

The concentration of Ag\(^+\) must be exceeded to initiate the precipitation of AgCl

\[ K_{sp} = [\text{Ag}^+] [\text{Cl}^-] = 1.6 \times 10^{-10} \]

\[ [\text{Ag}^+] = \frac{K_{sp}}{[\text{Cl}^-]} \]

\[ = \frac{(1.6 \times 10^{-10})}{(0.02)} \]

\[ = 8 \times 10^{-9} \text{ M} \]

Therefore [Ag\(^+\)] > 8 \times 10^{-9} \text{ M} is needed to initiate the precipitation of AgCl
Common ion effect and solubility

The solubility product is an equilibrium constant, and precipitation of an ionic substance from solution occurs whenever the ion product constant exceeds $K_{sp}$.

Example

$$AgNO_3 (s) \rightleftharpoons Ag^+(aq) + NO_3^-(aq)$$

The solubility equilibrium of AgCl is

$$AgCl (s) \rightleftharpoons Ag^+(aq) + Cl^-(aq)$$

If AgNO$_3$ is added to a saturated AgCl, the increase in [Ag$^+$] will make the ion product greater than the solubility product

$$Q = [Ag^+]_0 [Cl^-]_0$$

The effect of adding a common Ag ion, is a decrease in solubility of the AgCl salt in solution.
Problem

Calculate the solubility of silver chloride (AgCl) (g/L) in a $6.5 \times 10^{-3}$ $M$ silver nitrate (AgNO$_3$) solution.

AgNO$_3$ is a soluble strong electrolyte (it dissociates completely)

\[
\text{AgNO}_3(s) \rightleftharpoons \text{Ag}^+(aq) + \text{NO}_3^-(aq)
\]

\[
\begin{array}{ccc}
\text{Initial (M)} & 6.5 \times 10^{-3} & 0 \\
\text{Change (M)} & -s & +s & +s \\
\text{Equilibrium (M)} & s + 6.5 \times 10^{-3} & s
\end{array}
\]

\[
K_{sp} = [\text{Ag}^+] [\text{Cl}^-] = 1.6 \times 10^{-10}
\]

\[
1.6 \times 10^{-10} = (6.5 \times 10^{-3} + s) (s)
\]
\[ s = 2.5 \times 10^{-8} \text{ M} \]

At equilibrium

\[ [\text{Ag}^+] = (6.5 \times 10^{-3} + 2.5 \times 10^{-8}) = 6.5 \times 10^{-3} \text{ M} \]

\[ [\text{Cl}^-] = 2.5 \times 10^{-8} \text{ M} \]

Because all the Cl\(^-\) ions must come from AgCl, the amount of AgCl dissolved in AgNO\(_3\) solution also is 2.5 \times 10^{-8} \text{ M}. The calculation of the solubility of AgCl

Solubility of AgCl in AgNO\(_3\) solution

\[ = \frac{(2.5 \times 10^{-8} \text{ mol AgCl})}{(1 \text{ L soln})} \times \frac{(143.4 \text{ g AgCl})}{(1 \text{ mol AgCl})} \]

\[ = 3.6 \times 10^{-6} \text{ g/L} \]
pH and Solubility

The solubility of many substances depends on the pH of the solution.

Example

\[ \text{Mg(OH)}_2 (s) \rightleftharpoons \text{Mg}^{2+}(aq) + 2 \text{OH}^-(aq) \]

Adding OH\(^-\) ions shifts the equilibrium from right to left, decreasing the solubility of \(\text{Mg(OH)}_2\)

\[
\begin{array}{ccc}
\text{Mg(OH)}_2(s) & \rightleftharpoons & \text{Mg}^{2+}(aq) + 2 \text{OH}^-(aq) \\
\hline
\text{Initial (M)} & 0 & 0 \\
\text{Change (M)} & -s & +s & +2s \\
\text{Equilibrium (M)} & s & 2s
\end{array}
\]
\[ K_{sp} = [Mg^{2+}] [OH^-]^2 = 1.2 \times 10^{-11} \]

\[ K_{sp} = (s)(2s)^2 = 4s^3 \]

\[ s = 1.4 \times 10^{-4} M \]

At equilibrium

\[ [OH^-] = 2 \times 1.4 \times 10^{-4} M = 2.8 \times 10^{-4} M \]

\[ pOH = -\log(2.8 \times 10^{-4}) = 3.55 \]

\[ pH = 14.0 - 3.55 = 10.45 \]
The dissolution process and the effect of extra H\(^+\) can be summarized as

\[
\begin{align*}
Mg(OH)_2(s) & \rightleftharpoons Mg^{2+}(aq) + 2OH^-(aq) \\
2H^+(aq) + 2OH^-(aq) & \rightleftharpoons 2H_2O(l)
\end{align*}
\]

Overall: \[ Mg(OH)_2(s) + 2 H^+(aq) \rightleftharpoons Mg^{2+}(aq) + 2H_2O(aq) \]
Complex ion equilibria and solubility

Complex ion
An ion containing a central metal cation bonded to one or more molecules or ions

Transition metals have a particular tendency to form complex ions because they have incompletely filled \( d \) electronic subshell

Example

\[
\text{Co}^{2+}(aq) + 4\text{Cl}^-(aq) \rightleftharpoons \text{CoCl}_4^{2-}(aq)
\]

Formation constant
The equilibrium constant for the complex formation

Example

\[
\text{Cu}^{2+}(aq) + 4\text{NH}_3(aq) \rightleftharpoons \text{Cu(NH}_3)_4^{2+}(aq)
\]
\[ K_f = \frac{[Cu(NH_3)_4^{2+}]}{[Cu^{2+}][NH_3]^4} \]
\[ = 5.0 \times 10^{13} \]

The very large value of \( K_f \) indicates that the complex ion is very stable

**Problem**

Calculate the molar solubility of AgCl in a 1.0 \( M \) NH\(_3\) solution.

\[ AgCl(s) \rightleftharpoons Ag^+(aq) + Cl^-(aq) \]

The Ag\(^+\) ions form a complex ion with NH\(_3\)

\[ Ag^+(aq) + 2NH_3(aq) \rightleftharpoons Ag(NH_3)_2^+(aq) \]
\[ \text{AgCl(s)} \rightleftharpoons \text{Ag}^+(aq) + \text{Cl}^-(aq) \quad K_{sp} = [\text{Ag}^+] [\text{Cl}^-] = 1.6 \times 10^{-10} \]

\[ \text{Ag}^+(aq) + 2\text{NH}_3(aq) \rightleftharpoons \text{Ag(NH}_3\text{)}_2^+(aq) \quad K_f = [\text{Ag(NH}_3\text{)}_2^+] / ([\text{Ag}^+] [\text{NH}_3]^2) = 1.5 \times 10^7 \]

\[ \text{AgCl(s)} + 2\text{NH}_3(aq) \rightleftharpoons \text{Ag(NH}_3\text{)}_2^+(aq) + \text{Cl}^-(aq) \]

The equilibrium constant \( K \) is the product of the equilibrium constants of individual reactions

\[
K = K_{sp} K_f = [\text{Ag(NH}_3\text{)}_2^+] [\text{Cl}^-] / [\text{NH}_3]^2
\]

\[
= (1.6 \times 10^{-10}) (1.5 \times 10^7)
\]

\[
= 2.4 \times 10^{-3}
\]
Changes in concentrations that result from formation of the complex ion

\[
\begin{align*}
\text{AgCl(s) + 2NH}_3(aq) & \rightleftharpoons \text{Ag(NH}_3)_2^{+}(aq) + \text{Cl}^-(aq) \\
\text{Initial (M)} & \quad 1.0 & 0.0 & 0.0 \\
\text{Change (M)} & \quad -s & -2s & +s & +s \\
\text{Equilibrium (M)} & \quad (1.0 - 2s) & s & s \\
\end{align*}
\]

After formation a complex ion

\[
K = \frac{(s)(s)}{(1.0 - 2s)^2}
\]

\[
2.4 \times 10^{-3} = \frac{s^2}{(1.0 - 2s)^2}
\]

\[
s = 0.045 \text{ M}
\]

\[
[\text{Ag(NH}_3)_2^{+}] = 0.045 \text{ M}
\]
