IMPORTANT NOTICE

Texas Instruments Incorporated and its subsidiaries (TI) reserve the right to make corrections, modifications, enhancements, improvements, and other changes to its products and services at any time and to discontinue any product or service without notice. Customers should obtain the latest relevant information before placing orders and should verify that such information is current and complete. All products are sold subject to TI's terms and conditions of sale supplied at the time of order acknowledgment.

TI warrants performance of its hardware products to the specifications applicable at the time of sale in accordance with TI's standard warranty. Testing and other quality control techniques are used to the extent TI deems necessary to support this warranty. Except where mandated by government requirements, testing of all parameters of each product is not necessarily performed.

TI assumes no liability for applications assistance or customer product design. Customers are responsible for their products and applications using TI components. To minimize the risks associated with customer products and applications, customers should provide adequate design and operating safeguards.

TI does not warrant or represent that any license, either express or implied, is granted under any TI patent right, copyright, mask work right, or other TI intellectual property right relating to any combination, machine, or process in which TI products or services are used. Information published by TI regarding third party products or services does not constitute a license from TI to use such products or services or a warranty or endorsement thereof. Use of such information may require a license from a third party under the patents or other intellectual property of that third party, or a license from TI under the patents or other intellectual property of TI.

Reproduction of information in TI data books or data sheets is permissible only if reproduction is without alteration and is accompanied by all associated warranties, conditions, limitations, and notices. Reproduction of this information with alteration is an unfair and deceptive business practice. TI is not responsible or liable for such altered documentation.

Resale of TI products or services with statements different from or beyond the parameters stated by TI for that product or service voids all express and any implied warranties for the associated TI product or service and is an unfair and deceptive business practice. TI is not responsible or liable for any such statements.

About This Manual

This document is a companion to the TMS320 DSP Algorithm Standard Rules and Guidelines (literature number SPRU352) and contains all of the APIs that are defined by the TMS320 DSP Algorithm Interoperability Standard (also known as XDAIS) specification.

The TMS320 DSP algorithm standard is part of TI’s eXpressDSP technology initiative. Algorithms that comply with the standard are tested and awarded an “expressDSP-compliant” mark upon successful completion of the test.

Intended Audience

This document assumes that you are fluent in the C language, have a good working knowledge of digital signal processing and the requirements of DSP applications, and have had some exposure to the principles and practices of object-oriented programming. This document describes the interfaces between algorithms and the applications that utilize these algorithms. System integrators will see how to incorporate multiple algorithms from separate developers into a complete system. Algorithm writers will be able to determine the methods that must be implemented by eXpressDSP-compliant algorithms and how each method works in a system.

How to Use This Manual

This document contains the following chapters:

- **Chapter 1 – Abstract Algorithm Interfaces**, contains the abstract interfaces that are defined by this specification; all eXpressDSP-compliant algorithms must implement the IALG interface.
- **Chapter 2 – Runtime APIs**, contains runtime APIs for algorithms implementing the IDMA2 interface.
- **Chapter 3 - Supplementary APIs**, describes supplementary module APIs that are available to the clients of XDAIS algorithms but are not part of the core run-time support.
- **Appendix A – Source Code Examples**, contains complete source code examples of eXpressDSP-compliant algorithms.

Each interface defined in this document is presented in a common format. The interface documentation in each chapter is organized as a series of reference pages (first alphabetized by interface name and second by function name) that describes the programming interface for each function. Reference pages
are also included that describe the overall capabilities of each interface and appears prior to the functions defined by the interface.

Each function reference page includes the name of the function, number and type of all parameters and return values of the function, a brief description of the function, and all preconditions and postconditions associated with the function. Preconditions are conditions that must be satisfied prior to calling the function. Postconditions are all conditions that the function insures are true when the function returns.

Preconditions must be satisfied by the client while postconditions are ensured by the implementation. Application or framework developers must satisfy the preconditions, whereas developers who implement the interfaces must satisfy the postconditions.

Additional Documents and Resources

The TMS320 DSP Algorithm Standard specification is currently divided between two documents:

1) TMS320 DSP Algorithm Standard Rules and Guidelines (literature number SPRU352)
2) TMS320 DSP Algorithm API Reference (this document)

The TMS320 DSP Algorithm Standard Rules and Guidelines document not only describes all the rules and guidelines that make up the algorithm standard, but contains APIs that are required by the standard and full source examples of standard algorithm components as well.

The following documents contain supplementary information necessary to adhere to the TMS320 DSP Algorithm Standard specification:

- DSP/BIOS User’s Guide
- TMS320C54x/C6x/C2x Optimizing C Compiler User’s Guide

In addition to the previously listed documents, complete sources to modules and examples described in this document are included in the TMS320 DSP Developer’s Kit. This developer’s kit includes additional examples and tools to assist in both the development of XDAIS algorithms and the integration of these algorithms into applications.

Text Conventions

The following conventions are used in this specification:

- Text inside back-quotes (``) represents pseudo-code
- Program source code, function and macro names, parameters, and command line commands are shown in a **mono-spaced** font.

Abstract Algorithm Interfaces

This chapter describes all of the abstract interfaces that are defined by the XDAIS specification that apply to all algorithms.

- **IALG** – algorithm interface defines a framework independent interface for the creation of algorithm instance objects
- **IDMA2** - algorithm interface defining a uniform way to handle the DMA resource.

All XDAIS algorithms must implement the IALG interface. XDAIS algorithms that want to utilize the DMA resource must implement the IDMA2 interface and use the ACPY2 interface provided by the client to request DMA services. IDMA2 and ACPY2 APIs replace and deprecate the IDMA and ACPY interfaces that were defined in the earlier revisions of the *TMS320 DSP Algorithm Standard Rules and Guidelines* (SPRU352) and *TMS320 DSP Algorithm Standard API Reference* (SPRU360). Algorithms that have already been developed using the deprecated IDMA and ACPY APIs remain eXpressDSP-compliant; however, development of new algorithms should follow the new IDMA2/ACPY2 specification.

Modern component programming models support the ability of a single component to implement more than one interface. This allows a single component to be used concurrently by a variety of different clients. In addition to a component’s concrete interface (defined by its header) a component can, for example, support a trace interface that allows an in-field diagnostics subsystem to start, stop, and control the acquisition of data showing the component’s execution trace. If all traceable components implement a common abstract trace interface, tools and libraries can be written that can uniformly control the generation and display of trace information for all components in a system.
Support for multiple interfaces is often incorporated into the development environment using code wizards, the programming language itself, or both. Since the standard only requires the C language, the ability of a module to support multiple interfaces is awkward.

However, several significant benefits make this approach worthwhile. A vendor may opt to not implement certain interfaces for some components. New interfaces can be defined without affecting existing components, and partitioning a large interface into multiple simpler interfaces makes it easier to understand the component as a whole.

As described in the TMS320 DSP Algorithm Standard Rules and Guidelines document, interfaces are defined by header files; each header defines a single interface. A module’s header file is called a concrete interface. A special type of interface header is used to define an abstract interface. An abstract interface header is identical to a normal module interface header except that it declares a structure of function pointers named XYZ_Fxns. Abstract interfaces are so named because, it is possible that more than one module in a system implements them. A module ABC implements an abstract interface XYZ if it declares and initializes a static structure of type XYZ_Fxns named ABC_XYZ.

    *);

    1-6
Description The IALG interface is implemented by all algorithms in order to define their memory resource requirements and enable efficient use of on-chip data memories by client applications.

A module implements the IALG interface if it defines and initializes a global structure of type IALG_Fxns. For the most part, this means that every function defined in this structure must be implemented (and assigned to the appropriate field in this structure). Note that the first field of the IALG_Fxns structure is a Void * pointer. This field must be initialized to a value that uniquely identifies the module implementation. This same value must be used in all interfaces implemented by the module. Since all XDAIS algorithms must implement the IALG interface, it is sufficient for XDAIS algorithm modules to set this field to the address of the module’s declared IALG_Fxns structure.

In some cases, an implementation of IALG does not require any processing for a particular method. Rather than require the implementation to implement functions that simply return to the caller, implementations are allowed to set function pointer to NULL. This allows the client to avoid unnecessarily calling functions that do nothing and avoids the code space overhead of these functions.

The functions defined in IALG_Fxns fall into several categories.

1) Instance object creation, initialization, and deletion

2) Algorithmic processing

3) Instance object control and relocation

Instance object creation is complicated by removing memory allocation from the algorithm. In order for an algorithm to be used in a variety of applications, decisions about memory overlays and preemption
IALG – Algorithm Instance Interface

must be made by the client rather than the algorithm. Thus, it is important to give the client as much control over memory management as possible. The functions `algAlloc()`, `algInit()`, and `algFree()` allow the algorithm to communicate its memory requirements to the client, let the algorithm initialize the memory allocated by the client, and allow the algorithm to communicate the memory to be freed when an instance is no longer required. Note that these operations are not called in time-critical sections of an application.

Please note that the following enhancement affecting allocation, management, and sharing of memory resources is introduced in the current revision of this document (SPRU360C).

- The algorithm may now provide the client, during the `algAlloc()` call, the base address of any statically initialized IALG_WRITEONCE persistent buffer it is requesting. If the algorithm provides a base address, the client may simply use it to initialize the instance object without allocating any additional memory; otherwise, the client allocates and grants the memory as if it is a standard memory request. However, the client may arrange sharing of write-once persistent buffers by granting multiple instances of the same algorithm created with identical parameters, the same set of write-once persistent buffers. This enhancement provides a simple mechanism for sharing run-time relocatable read-only look-up tables.

Once an algorithm instance object is created, it can be used to process data in real-time. The subclasses of IALG define other entry points to algorithmic processing supported by eXpressDSP-compliant algorithms. Prior to invoking any of these methods, clients are required to activate the instance object via the `algActivate()` method. The `algActivate()` method provides a notification to the algorithm instance that one or more algorithm processing methods is about to be run zero or more times in succession. After the processing methods have been run, the client calls the `algDeactivate()` method prior to reusing any of the instance’s scratch memory. The `algActivate()` and `algDeactivate()` methods give the algorithm a chance to initialize and save scratch memory that is outside the main algorithm-processing loop defined by its extensions of the IALG interface.

The final two methods defined by the IALG interface are `algControl()` and `algMoved()`. The `algControl()` operation provides a standard way to control an algorithm instance and receive status information from the algorithm in real-time. The `algMoved()` operation allows the client to move an algorithm instance to physically different memory. Since the algorithm instance object may contain references to the internal buffer that may be moved by the client, the client is required to call the `algMoved()` method whenever the client moves an object instance.

The following figure summarizes the only valid sequences of execution of the IALG_Fxns functions for a particular algorithm instance.
For simplicity, the \texttt{algControl()} and \texttt{algNumAlloc()} operations are not shown above. The \texttt{algControl()} method may be called at any time after \texttt{algInit()} and any time before \texttt{algFree()}. The \texttt{algNumAlloc()} method may be called at any time.

\textbf{Algorithm Parameters and Status} When algorithm instances are created, the client can pass algorithm-specific parameters to the \texttt{algAlloc()} and the \texttt{algInit()} methods. To support implementation-specific extensions to standard abstract algorithm interfaces, every algorithm’s parameter structure must begin with the \texttt{size} field defined in the IALG\_Params structure. This field is set by the client to the size of the parameter structure (including the size field itself) that is being passed to the algorithm implementation. Thus, the implementation can “know” if the client is passing just the standard parameter set or an extended parameter set. Conversely, the client can elect to send just the “standard” parameters or an implementation specific set of parameters. Of course, if a client uses an implementation specific set, the client cannot be used with a different implementation of the same algorithm.

```c
client()
{
    FIR_Params stdParams;
    FIR_TI_Params tiParams;

    stdParams = FIR_PARAMS; // initialize all fields to defaults */
    stdParams.coeff = ...; // initialize selected parameters */
    fxns->algAlloc(&stdParams, ...); // pass parameters to algorithm */

    tiParams = FIR_TI_PARAMS; // initialize all fields to defaults */
    tiParams.coeff = ...; // initialize selected parameters */
    fxns->algAlloc(&tiParams, ...); // pass parameters to algorithm */
}
```
IALG – Algorithm Instance Interface

Int FIR_TI_algAlloc(IALG_Params *clientParams, ...) {
    FIR_TI_Params params = FIR_TI_PARAMS;
    /* client passes in parameters, use them to override defaults */
    if (clientParams != NULL) {
        memcpy(&params, clientParams, clientParams->size);
    }
    /* use params as the complete set of parameters */
}

From the code fragments above, you can see that the client uses the same style of parameter passing when passing generic parameters or implementation-specific parameters. A client may do both. The implementation can also easily deal with either set of parameters. The only requirement is that the generic parameters always form a prefix of the implementation specific parameters; i.e., any implementation specific parameter structure must always include the standard parameters as its first fields.

This same technique is used to extend the algorithm status structures. In this case, however, all algorithm status structures start with the IALG_Status fields.

Example Algorithms that implement the IALG interface enable run-time instance creation using the following generic create and delete functions.

#define MAXMEMRECS 16
typedef struct IALG_Obj {
    IALG_Fxns fxns; /* algorithm functions */
} IALG_Obj;
IALG_Handle ALG_create(IALG_Fxns *fxns, IALG_Params *params) {
    IALG_MemRec memTab[MAXMEMRECS];
    IALG_Handle alg = NULL;
    Int n;
    IALG_Fxns *fxnsPtr = NULL;
    IALG_Handle p = NULL;
    if (fxns->algNumAlloc() <= MAXMEMRECS) {
        n = fxns->algAlloc(params, &fxnsPtr, memTab);
        if (fxnsPtr != NULL) {
            if ((p = ALG_create(fxnsPtr, NULL)) == NULL)
                return ((IALG_Handle) NULL);
        }
        if (allocMemory(memTab, n)) {
            alg = (IALG_Handle)memTab[0].base;
            alg->fxns = fxns;
            if (fxns->algInit(alg, memTab, p, params) != IALG_EOK) {
                fxns->algFree(alg, memTab);
                freeMemory(memTab, n);
                alg = NULL;
            }
        }
    }
}

1-10
In order to implement the IALG interface, all algorithm objects must be defined with \texttt{IALG\_Obj} as their first field. This insures that all pointers to algorithm objects can be treated as pointers to \texttt{IALG\_Obj} structures.

The framework functions outlined above are just examples of how to use the IALG functions to create a simple object create and delete function. Other frameworks might create objects very differently. For example, one can imagine a framework that creates multiple objects at the same time by first invoking the \texttt{algAlloc()} function for all objects, optimally allocating memory for the entire collection of objects, and then completing the initialization of the objects. By considering the memory requirements of all objects prior to allocation, such a framework can more optimally assign memory to the required algorithms.

Once an algorithm object instance is created it can be used to process data. However, it is important that if the algorithm defines \texttt{algActivate()} and \texttt{algDeactivate()} methods, then these must bracket the execution of any of the algorithm’s processing functions. The following function could be used, for example, to execute any implementation of the IFIR interface on a set of buffers.

\begin{verbatim}
Void FIR_apply(FIR_Handle alg, Int *in[], Int *out[]) {
   /* do app specific initialization of scratch memory */
   if (alg->fxns->ialg.algActivate != NULL) {
      alg->fxns->ialg.algActivate(alg);
   }
   /* filter data */
   alg->fxns->filter(alg, in, out);
   /* do app specific store of persistent data */
   if (alg->fxns->ialg.algDeactivate != NULL) {
      alg->fxns->ialg.algDeactivate(alg);
   }
}
\end{verbatim}

This implementation of \texttt{FIR\_apply()} assumes that all persistent memory is not shared; thus, it does not restore this data prior to calling \texttt{algActivate()} and it does not save this memory after \texttt{algDeactivate()}. If a framework shares persistent data among algorithms, it must insure that this data is properly restored prior to running any processing methods of the algorithms.

If an algorithm’s processing functions are always executed as shown in the \texttt{FIR\_apply()} function above, there is no need for the \texttt{algActivate()} and \texttt{algDeactivate()} functions. To save the overhead of making two function calls, their functionality would be folded into the processing functions. The purpose of \texttt{algActivate()} and \texttt{algDeactivate()} is to enable the algorithm’s processing functions to be called multiple times between calls to \texttt{algActivate()} and \texttt{algDeactivate()}. This allows the algorithm writer the option of factoring data initialization functions, such as initialization of scratch memory, into the \texttt{algActivate()} function. The overhead of this data movement can then be amortized across multiple calls to processing functions.

See the example of a simple \texttt{FIR\_TI} filter module that implements the IALG interface (in Appendix A). The \texttt{algActivate()} function copies filter history and coefficients into scratch DARAM, the \texttt{algDeac-
tivate() function copies history data to external persistent memory, and the filter function treats the filter coefficient and history memory as persistent data. In this example, the filter function can optimally process the data by minimizing the per frame overhead associated with saving and restoring persistent data.
**algActivate** – initialize scratch memory buffers prior to processing

**Name**

algActivate – initialize scratch memory buffers prior to processing

**Synopsis**

Void algActivate(IALG_Handle handle);

**Arguments**

IALG_Handle handle; /* algorithm instance handle */

**Return Value**

Void

**Description**

algActivate() initializes any of the instance’s scratch buffers using the persistent memory that is part of the algorithm’s instance object.

The first (and only) argument to algActivate() is an algorithm instance handle. This handle is used by the algorithm to identify the various buffers that must be initialized prior to calling any of the algorithm’s processing methods.

The implementation of algActivate() is optional. The algActivate() method should only be implemented if a module wants to factor out initialization code that can be executed once prior to processing multiple consecutive frames of data.

If a module does not implement this method, the algActivate field in the module’s static function table (of type IALG_Fxns) must be set to NULL. This is equivalent to the following implementation:

```c
Void algActivate(IALG_Handle handle)
{
}
```

**Preconditions**

The following conditions must be true prior to calling this method; otherwise, its operation is undefined.

- algActivate() can only be called after a successful return from algInit().
- handle must be a valid handle for the algorithm’s instance object.
- No other algorithm method is currently being run on this instance. This method never preempts any other method on the same instance.
- If the algorithm has implemented the IDMA2 interface, algActivate() can only be called after a successful return from dmaInit().

**Postconditions**

The following condition is true immediately after returning from this method.

- All methods related to the algorithm may now be executed by client (subject to algorithm specific restrictions).

**Example**

```c
typedef struct EncoderObj {
    IALG_Obj ialgObj;    /* IALG object MUST be first field */
    Int *workBuf;        /* pointer to on-chip scratch memory */
    Int *historyBuf;     /* previous frame’s data in ext mem */
    ...;
} EncoderObj;
```
**algActivate** – initialize scratch memory buffers prior to processing

Void algActivate(IALG_Handle handle)
{  
    EncoderObj *inst = (EncoderObj *)handle;
    
    /* copy history to beginning of on-chip working buf */
    memcpy(inst->workingBuf, inst->histBuf, HISTSIZE);
}

Void encode(IALG_Handle handle,  
            Void *in[], Void *out[])
{  
    EncoderObj *inst = (EncoderObj *)handle;

    /* append input buffer to history in on-chip workBuf */
    memcpy(inst->workBuf + HISTSIZE, in, HISTSIZE);

    /* encode data */
    ...
    /* move history to beginning of workbuf for next frame */
    memcpy(inst->workBuf, inst->workingBuf + FRAMESIZE, HISTSIZE);
}

Void algDeactivate(IALG_Handle handle)
{  
    EncoderObj *inst = (EncoderObj *)handle;

    /* save beginning of on-chip workBuf to history */
    memcpy(inst->histBuf, inst->workingBuf, HISTSIZE);
}

See Also algDeactivate()
**Abstract Algorithm Interfaces**

---

### Name

algAlloc() – get algorithm object’s memory requirements

### Synopsis

```c
numRecs = algAlloc(const IALG_Params *params, IALG_Fxns **parentFxns, IALG_MemRec memTab[]);
```

### Arguments

- `IALG_Params *params;` /* algorithm specific attributes */
- `IALG_Fxns **parentFxns;` /* output parent algorithm functions */
- `IALG_MemRec memTab[];` /* output array of mem records */

### Return Value

`Int numRecs;` /* number of initialized records in memTab[] */

### Description

algAlloc() returns a table of memory records that describe the size, alignment, type and memory space of all buffers required by an algorithm (including the algorithm’s instance object itself). If successful, this function returns a positive non-zero value indicating the number of records initialized. This function can never initialize more memory records than the number returned by algNumAlloc(). If algNumAlloc() is not implemented, the maximum number of initialized memory records is IALG_DEFMEMRECS.

The first argument to algAlloc() is a pointer to the creation arguments for the instance of the algorithm object to be created. This pointer is algorithm-specific; i.e., it points to a structure that is defined by each particular algorithm. This pointer may be NULL; however, in this case, algAlloc(), must assume default creation parameters and must not fail.

The second argument to algAlloc() is an output parameter. algAlloc() may return a pointer to its parent’s IALG functions. If this output value is assigned a non-NULL value, the client must create the parent instance object using the designated IALG functions pointer. The parent instance object must then be passed to algInit().

algAlloc() may be called at any time and it must be idempotent; i.e., it can be called repeatedly without any side effects and always returns the same result.

### Preconditions

The following conditions must be true prior to calling this method; otherwise, its operation is undefined.

- The number of memory records in the array `memTab[]` is no less than the number returned by algNumAlloc().
- `*parentFxns` is a valid pointer to an IALG_Fxns pointer variable.
- The `params` parameter may be NULL.

### Postconditions

The following conditions are true immediately after returning from this method.

- If the algorithm needs a parent object to be created, the pointer `*parentFxns` is set to a non-NULL value that points to a valid IALG_Fxns structure, the parent’s IALG implementation. Otherwise, this pointer is not set. algAlloc() may elect to ignore the `parentFxns` pointer altogether.
algAlloc() – get algorithm object’s memory requirements

- For each memory descriptor in memTab with an IALG_WRITEONCE attribute, the algorithm has either set the base field to a non-NULL value, which is the address of a statically allocated and initialized memory buffer of the indicated ‘size,’ or has set the base field to NULL, thereby requiring the memory for the buffer to be provided by the client.

- Exactly \(n\) elements of the memTab[] array are initialized, where \(n\) is the return value from this operation.

- For each memory descriptor in memTab with an IALG_PERSIST or IALG_SCRATCH attribute, the algorithm does not set its base field.

- If the params parameter is NULL, the algorithm assumes default values for all fields defined by the parameter structure.

- memTab[0] defines the memory required for the instance’s object and this object’s first field is an IALG_Obj structure.

- memTab[0] is requested as persistent memory.

If the operation succeeds, the return value of this operation is greater than or equal to one. Any other return value indicates that the parameters specified by params are invalid.

Example

typedef struct EncoderObj {
    IALG_Obj ialgObj /* IALG object MUST be first field */
    Int *workBuf; /* pointer to on-chip scratch memory */
    Int workBufLen; /* expressed in words per frame */
    ...
} EncoderObj;

typedef struct EncoderParams {
    Int frameDuration; /* expressed in ms per frame */
};
EncoderParams ENCODERATTRS = {5}; /* default parameters */

Int algAlloc(IALG_Params *algParams, IALG_Fxns **p, IALG_MemRec memTab[]) {
    EncoderParams *params = (EncoderParams *)algParams;

    if (params == NULL) {
        params = &ENCODERATTRS; /* use default parameters */
    }

    memTab[0].size = sizeof (EncoderObj);
    memTab[0].alignment = 0;
    memTab[0].type = IALG_PERSIST;
    memTab[0].space = IALG_EXTERNAL;

    memTab[1].size = params->frameDuration * 8 * sizeof(int);
    memTab[1].alignment = 0; /* no alignment */
    memTab[1].type = IALG_PERSIST;
    memTab[1].space = IALG_DARAM; /* dual-access on-chip */
algAlloc() — get algorithm object's memory requirements

```c
memTab[2].size = sizeof(G729D_VND_EncoderTable);
memTab[2].alignment = 0; /* no alignment */
memTab[2].type = IALG_WRITEONCE;
memTab[2].space = IALG_SARAM; /* single-access on-chip */
memTab[2].base = &G729D_VND_EncoderTable; /* shared look-up table */

return (3);
```

See Also algFree()
**algControl – algorithm specific control and status**

**Name**

```
algControl – algorithm specific control and status
```

**Synopsis**

```
retval = algControl(IALG_Handle handle,
                   IALG_Cmd cmd, IALG_Status *status);
```

**Arguments**

```
IALG_Handle  handle;   /* algorithm instance handle */
IALG_Cmd     cmd;      /* algorithm specific command */
IALG_Status  *status;  /* algorithm specific status */
```

**Return Value**

```
Int retval;
```

**Description**

`algControl()` sends an algorithm specific command, `cmd`, and an input/output status buffer pointer to an algorithm’s instance object.

The first argument to `algControl()` is an algorithm instance handle. `algControl()` must only be called after a successful call to `algInit()` but may be called prior to `algActivate()`. `algControl()` must never be called after a call to `algFree()`.

The second and third parameters are algorithm (and possible implementation) specific values. Algorithm and implementation-specific `cmd` values are always less than `IALG_SYSCMD`. Greater values are reserved for future upward-compatible versions of the IALG interface.

Upon successful completion of the control operation, `algControl()` returns `IALG_EOK`; otherwise it returns `IALG_EFAIL` or an algorithm specific error return value.

In preemptive execution environments, `algControl()` may preempt a module’s other methods (for example, its processing methods).

The implementation of `algControl()` is optional. If a module does not implement this method, the `algControl` field in the module’s static function table (of type `IALG_Fxns`) must be set to `NULL`. This is equivalent to the following implementation:

```
Int algControl(IALG_Handle handle,
               IALG_Cmd cmd, IALG_Status *status)
{
    return (IALG_EFAIL);
}
```

**Preconditions**

The following conditions must be true prior to calling this method; otherwise, its operation is undefined.

- `algControl()` can only be called after a successful return from `algInit()`.
- `handle` must be a valid handle for the algorithm’s instance object.
- Algorithm specific `cmd` values are always less than `IALG_SYSCMD`.

**Postconditions**

The following conditions are true immediately after returning from this method.

- If the control operation is successful, the return value from this operation, `retval`, is equal to `IALG_EOK`; otherwise it is equal to either `IALG_EFAIL` or an algorithm specific return value.
If the cmd value is not recognized, the return value from this operation, retval, is not equal to IALG_EOK.

**Example**

typedef struct EncoderStatus {
    Bool voicePresent; /* voice in current frame? */
    ...;
} EncoderStatus;

typedef enum {EncoderGetStatus, ...} EncoderCmd;

Int algControl(IALG_Handle handle,
               IALG_Cmd cmd, IALG_Status *status)
{
    EncoderStatus *sptr = (EncoderStatus *)status;

    switch ((EncoderCmd)cmd) {
        case EncoderGetStatus:
            sptr->voicePresent = ...;
            ...;
        case EncoderSetMIPS:
            ...;
    }
}

algDeactivate – save all persistent data to non-scratch memory

<table>
<thead>
<tr>
<th>Name</th>
<th>algDeactivate – save all persistent data to non-scratch memory</th>
</tr>
</thead>
<tbody>
<tr>
<td>Synopsis</td>
<td>Void algDeactivate(IALG_Handle handle);</td>
</tr>
<tr>
<td>Arguments</td>
<td>IALG_Handle handle; /* algorithm instance handle */</td>
</tr>
<tr>
<td>Return Value</td>
<td>Void</td>
</tr>
</tbody>
</table>

Description  
algDeactivate() saves any persistent information to non-scratch buffers using the persistent memory that is part of the algorithm’s instance object.

The first (and only) argument to algDeactivate() is an algorithm instance handle. This handle is used by the algorithm to identify the various buffers that must be saved prior to the next cycle of algActivate() and processing.

The implementation of algDeactivate() is optional. The algDeactivate() method is only implemented if a module wants to factor out initialization code that can be executed once prior to processing multiple consecutive frames of data.

If a module does not implement this method, the algDeactivate field in the module’s static function table (of type IALG_Fxns) must be set to NULL. This is equivalent to the following implementation:

```c
Void algDeactivate(IALG_Handle handle)
{
}
```

Preconditions  
The following conditions must be true prior to calling this method; otherwise, its operation is undefined.

- algDeactivate() can only be called after a successful return from algInit().
- The instance object is currently “active”; i.e., all instance memory is active and if an algActivate() method is defined, it has been called.
- handle must be a valid handle for the algorithm’s instance object.
- No other algorithm method is currently being run on this instance. This method never preempts any other method on the same instance.

Postconditions  
The following conditions are true immediately after returning from this method.

- No methods related to the algorithm may now be executed by client; only algActivate() or algFree() may be called.
- All instance scratch memory may be safely overwritten.

algActivate()
**Name**

algFree – get algorithm object’s memory requirements

**Synopsis**

numRecs = algFree(IALG_Handle handle, IALG_MemRec memTab[]);

**Arguments**

IALG_Handle handle;  /* algorithm instance handle */
IALG_MemRec memTab[]; /* output array of mem records */

**Return Value**

Int numRecs; /* number of initialized records in memTab[] */

**Description**

algFree() returns a table of memory records that describe the base address, size, alignment, type, and memory space of all buffers previously allocated for the algorithm’s instance (including the algorithm’s instance object itself) specified by handle. This function always returns a positive non-zero value indicating the number of records initialized. This function can never initialize more memory records than the value returned by algNumAlloc().

**Preconditions**
The following conditions must be true prior to calling this method; otherwise, its operation is undefined.

- The memTab[] array contains at least algNumAlloc() records.
- handle must be a valid handle for the algorithm’s instance object.
- If the prior call to algAlloc() returned a non-NULL parent functions pointer, then the parent instance must be an active instance object created via that function pointer.
- No other algorithm method is currently being run on this instance. This method never preempts any other method on the same instance.

**Postconditions**
The following conditions are true immediately after returning from this method.

- memTab[] contains pointers to all of the memory passed to the algorithm via algInit().
- The size and alignment fields contain the same values passed to the client via the algAlloc() method; i.e., if the client makes changes to the values returned via algAlloc() and passes these new values to algInit(), the algorithm is not responsible for retaining any such changes.

**Example**

typedef struct EncoderObj {
   IALG_Obj ialgObj /* IALG object MUST be first field */
   Int *workBuf;
   Int workBufLen;
   ...;
} EncoderObj;

Int algFree(IALG_Handle handle, IALG_MemRec memTab[])
{
   EncoderObj *inst = (EncoderObj *)handle;
   algAlloc(NULL, memTab); /* get default values first */
   memTab[0].size = sizeof (EncoderObj);
algFree – get algorithm object’s memory requirements

```c
Int algAlloc(IALG_Params *params, IALG_MemRec memTab[])
{

    memTab[0].size = sizeof (EncoderObj);
    memTab[0].alignment = 1;
    memTab[0].type = IALG_PERSIST;
    memTab[0].space = IALG_EXTERNAL;
    memTab[1].size = 80;  /* 10ms @ 8KHz */
    memTab[1].alignment = 1;    /* no alignment */
    memTab[1].type = IALG_PERSIST;
    memTab[1].space = IALG_DARAM;  /* dual-access on-chip */

    return (2);
}
```

**See Also**

algAlloc()

In the example code above, `algAlloc()` is called inside `algFree()` to set four out of the five fields in each of the records in `memTab[]`. The purpose of this is to procure some code size optimization by avoiding repetition in `algFree()` of the same code already contained inside `algAlloc`.

However, careful consideration must be given to this type of optimization since `algFree` does not take a `params` argument, while `algAlloc` does. Some of the fields in a `memTab` record, typically size, will depend on the `params` argument. Inside `algFree` we are forced to call `algAlloc` with NULL (default) `params`. This value of `params` may not correspond to the value passed to the original call to `algAlloc` performed by the client when the algorithm object was instantiated. Because of this, if there are fields in a `memTab[]` record that depend on `params`, this information must also be stored within the instance object. After `algAlloc` is called inside `algFree`, the corresponding fields in the `memTab[]` records should be overwritten to reflect the information stored in the instance object. In the example above, the `size` field shows this type of behavior.
algInit – initialize an algorithm’s instance object

Name

algInit – initialize an algorithm’s instance object

Synopsis

status = algInit(IALG_Handle handle, IALG_MemRec memTab[],
                IALG_Handle parent, IALG_Params *params,);

Arguments

IALG_Handle handle; /* algorithm’s instance handle */
IALG_memRec memTab[]; /* array of allocated buffers */
IALG_Handle parent; /* handle algorithm’s parent instance */
IALG_Params *params; /* ptr to algorithm’s instance args */

Return Value

Int  status; /* status indicating success or failure */

Description

algInit() performs all initialization necessary to complete the run-time creation of an algorithm’s instance object. After a successful return from algInit(), the algorithm’s instance object is ready to be used to process data.

The first argument to algInit() is an algorithm instance handle. Handle is a pointer to an initialized IALG_Obj structure. Its value is identical to the memTab[0].base.

The second argument is a table of memory records that describe the base address, size, alignment, type, and memory space of all buffers allocated for an algorithm instance (including the algorithm’s instance object itself. The number of initialized records is identical to the number returned by a prior call to algAlloc()).

The third argument is a handle to another algorithm instance object. This parameter is often NULL; indicating that no parent object exists. This parameter allows clients to create a shared algorithm instance object and pass it to other algorithm instances. For example, a parent instance object might contain global read-only tables that are used by several instances of a vocoder.

The last argument is a pointer to algorithm-specific parameters that are necessary for the creation and initialization of the instance object. This pointer points to the same parameters passed to the algAlloc() operation. However, this pointer may be NULL. In this case, algInit(), must assume default creation parameters.

The client is not required to satisfy the IALG_MemSpace attribute of the requested memory. Note however that C6000 algorithms that use DMA may strictly require the client to satisfy its on-chip memory requirements and may not function correctly otherwise.

The client may allocate the requested IALG_WRITEONCE buffers once (or never, if the algorithm has assigned a base address in the prior call to algAlloc) and use the same buffers to initialize multiple instances of the same algorithm that are created with identical parameters.

Preconditions

The following conditions must be true prior to calling this method; otherwise, its operation is undefined.

Abstract Algorithm Interfaces 1-23
algInit – initialize an algorithm’s instance object

- memTab[] contains pointers to non-overlapping buffers with the size and alignment requested via a prior call to algAlloc(). In addition, the algorithm parameters, params, passed to algAlloc() are identical to those passed to this operation.

- handle must be a valid handle for the algorithm’s instance object; i.e., handle == memTab[0].base and handle->fxns is initialized to point to the appropriate IALG_Fxns structure.

- If the prior call to algAlloc() has not assigned a non-NULL base address to an IALG_WRITEONCE memTab[] entry, the client must provide the memory resource with the requested size and alignment.

- If the prior call to algAlloc() returned a non-NULL parent functions pointer, then the parent handle, parent, must be a valid handle to an instance object created via that function pointer.

- No other algorithm method is currently being run on this instance. This method never preempts any other method on the same instance.

- If parent is non-NULL, no other method is currently being run on the parent instance; i.e., this method never preempts any other method on the parent instance.

- If the prior call to algAlloc() assigned a non-NULL base address to an IALG_WRITEONCE memTab[] entry, the client may pass back the same address in the base field without allocating additional memory for that persistent write-once buffer. Alternatively, the client may treat IALG_WRITEONCE buffers in the same way as IALG_PERSIST buffers; by allocating new memory and granting it to the algorithm using the base field.

- The buffer pointed to in memTab[0] is initialized with a pointer to the appropriate IALG_Fxns structure followed by all 0s.

**Postconditions** The following conditions are true immediately after returning from this method.

- With the exception of any initialization performed by algActivate() and dmaInit(), all of the instance’s persistent and write-once memory is initialized and the object is ready to be used.

- All subsequent memory accesses to the IALG_WRITEONCE buffers by this algorithm instance will be read-only.

- If the algorithm has implemented the IDMA2 interface, the dmaGetChannels() operation can be called.
algInit – initialize an algorithm's instance object

Example

typedef struct EncoderObj {
    IALG_Obj ialgObj /* IALG object MUST be first field */
    int workBuf; /* pointer to on-chip scratch memory */
    int workBufLen; /* workBuf length (in words) */
    ...
} EncoderObj;

Int algInit(IALG_Handle handle,
            IALG_MemRec memTab[], IALG_Handle p, IALG_Params *algParams)
{
    EncoderObj *inst = (EncoderObj *)handle;
    EncoderParams *params = (EncoderParams *)algParams;

    if (params == NULL) {
        params = &ENCODERATTRS; /* use default parameters */
    }

    inst->workBuf = memTab[1].base;
    inst->workBufLen = params->frameDuration * 8;
    ...

    return (IALG_EOK);
}

See Also algAlloc(), algMoved()
algMoved – notify algorithm instance that instance memory has been relocated

Name

algMoved – notify algorithm instance that instance memory has been relocated

tSynopsis

Void algMoved(IALG_Handle handle,
             const IALG_MemRec memTab[], IALG_Handle
             parent, const IALG_Params *params);

Arguments

IALG_Handle handle;   /* algorithm's instance handle */
IALG_Handle parent;   /* handle algorithm's parent instance */
IALG_Params *params;  /* ptr to algorithm's instance args */
IALG_memRec memTab[]; /* array of allocated buffers */

Return Value

Void

Description

algMoved() performs any reinitialization necessary to insure that, if an algorithm's
instance object has been moved by the client, all internal data references are recomputed.

The arguments to algMoved() are identical to the arguments passed to algInit(). In fact, in many
cases an algorithm may use the same function defined for algInit() to implement algMoved().
However, it is important to realize that algMoved() is called in real-time whereas algInit() is not.
Much of the initialization required in algInit() does not need to occur in algMoved(). The client
is responsible for copying the instance's state to the new location and only internal references need to
be recomputed.

Although the algorithm's parameters are passed to algMoved(), with the exception of pointer values,
their values must be identical to the parameters passed to algInit(). The data referenced by any
pointers in the params structure must also be identical to the data passed to algInit(). The locations
of the values may change but their values must not.

The implementation of algMoved() is optional. However, it is highly recommended that this method
be implemented. If a module does not implement this method, the algMoved field in the module's static
function table (of type IALG_Fxns) must be set to NULL. This is equivalent to asserting that the algo-

rithm's instance objects cannot be moved.

Preconditions

The following conditions must be true prior to calling this method; otherwise, its opera-
tion is undefined.

- memTab[] contains pointers to all of the memory requested via a prior call to algAlloc(). The
  algorithm parameters, params, passed to algInit() are identical to those passed to this op-
  eration with the exception that pointer parameters may point to different locations, but their con-
  tents (what they point to) must be identical to what was passed to algInit().

- All buffers pointed to by memTab[] contain exact copies of the data contained in the original
  instance object at the time the object was moved.

- handle must be a valid handle for the algorithm's instance object; i.e., handle == mem-
  Tab[0].base and handle->fxns is initialized to point to the appropriate IALG_Fxns struc-

1-26
algMoved – notify algorithm instance that instance memory has been relocated

- If the prior call to `algInit()` was passed a non-NULL parent handle, then the parent handle, `parent`, must also be a valid handle to an instance object created with the parent’s IALG function pointer.

- `algMoved()` is invoked only when the original instance object is active; i.e., after `algActivate()` and before `algDeactivate()`. This allows `algMoved` to be able to reference both its scratch and persistent memory.

- No other algorithm method is currently being run on this instance. This method never preempts any other method on the same instance.

**Postconditions**  The following condition is true immediately after returning from this method.

- The instance object is functionally identical to the original instance object. It can be used immediately with any of the algorithm’s methods.

**Example**

```c
typedef struct EncoderObj {
    IALG_Obj ialgObj /* IALG object MUST be first field */
    int workBuf;    /* pointer to on-chip scratch memory */
    Int workBufLen; /* workBuf length (in words) */
    ...
} EncoderObj;
```

```c
algMoved(IALG_Handle handle, IALG_MemRed memTab[],
         IALG_Handle parent, IALG_Params *algParams)
{
    EncoderObj *inst = (EncoderObj *)handle;
    inst->workBuf = memTab[1].base;
}
```

**See Also**  `algInit()`
algNumAlloc() – number of memory allocation requests required

Name

Synopsis

Arguments

Return Value

Description algNumAlloc() returns the maximum number of memory allocation requests that the algAlloc() method requires. This operation allows clients to allocate sufficient space to call the algAlloc() method or fail because insufficient space exists to support the creation of the algorithm's instance object. algNumAlloc() may be called at any time and it must be idempotent; i.e., it can be called repeatedly without any side effects and always returns the same result.

algNumAlloc() is optional; if it is not implemented, the maximum number of memory records for algAlloc() is assumed to be IALG_DEFMEMRECS. This is equivalent to the following implementation:

```c
Int algNumAlloc(Void)
{
    return (IALG_DEFNUMRECS);
}
```

If a module does not implement this method, the algNumAlloc field in the module's static function table (of type IALG_Fxns) must be set to NULL.

Postconditions The following condition is true immediately after returning from this method.

- The return value from algNumAlloc() is always greater than or equal to one and always equals or exceeds the value returned by algAlloc().

Example The example below shows how an algorithm can use another algorithm.

```c
#define NUMBUF 3 /* max number of my memory requests */
extern IALG_Fxns *subAlg; /* sub-algorithm used by this alg */

Int algNumAlloc(Void)
{
    return (NUMBUF + subAlg->algNumAlloc());
}

Int algAlloc(const IALG_Params *p, struct IALG_Fxns **pFxns,
             IALG_MemRec memTab)
{
    Int n;

    /* initialize my memory requests */
    ...
    /* initialize sub-algorithm’s requests */
    n = subAlg->algAlloc(..., memTab);
    return (n + NUMBUF);
}
```

#define */ IDMA2_ */

**Description**  The IDMA2 interface is implemented by algorithms that utilize the DMA resource.

A module implements the IDMA2 interface if it defines and initializes a global structure of type IDMA2_Fxns. Every function defined in this structure must be implemented and assigned to the appropriate field in this structure. Note that the first field of the IDMA2_Fxns structure is a Void * pointer. This field must be initialized to a value that uniquely identifies the module’s implementation. This same value must be used in all interfaces implemented by the module. Since all compliant algorithms must implement the IALG interface, it is sufficient for these algorithms to set this field to the address of the module’s declared IALG_Fxns structure.

Figure 1-3 illustrates the IDMA2 functions calling sequence, and also how it relates to the IALG functions.

**Figure 1-3. IDMA2 Functions Calling Sequence**

![Diagram of IDMA2 Functions Calling Sequence](image)

Note that the dmaChangeChannels() and dmaGetChannels() operations can be called at any time in the algorithm’s real-time stages. The algMoved() and algNumAlloc() functions are omitted for simplicity.

The important point to notice in the figure above, is that dmaGetChannels() and dmaInit() operations must be called after algInit() and before algActivate().

dmaGetChannelCnt() can be called before the algorithm instance object is created if the framework wants to query the algorithm of its DMA resource requirements before creating the instance object.
System Overview  Figure 1-6 illustrates a system with an algorithm implementing the IALG and IDMA2 interfaces and the application with a DMA manager. Notice that the algorithm calls the ACPY2 runtime APIs, which is implemented by the application’s DMA manager. The ACPY2 interface describes the comprehensive list of DMA functions an algorithm can call using the DMA handles to program the logical DMA channels obtained through the IDMA2 protocol. These functions allow the algorithm to:

- Configure each logical channel’s DMA transfer settings
- Submit asynchronous DMA transfer requests
- Synchronize with completion status of submitted transfers (both blocking and non-blocking)

Logical DMA Channels

Algorithms request DMA services using the hardware abstraction layer described by the IDMA2 and ACPY2 interfaces. Each DMA handle received through the IDMA2_ChannelRec structure provides the algorithm a dedicated, private DMA channel. Each logical DMA channel retains the most recent configuration settings applied by the algorithm and uses those settings when a DMA transfer request is submitted. The physical DMA transfer takes place asynchronously by the available physical hardware under the operational control of the ACPY2 implementation library provided by the client. The same physical DMA resource may be transparently shared among several logical channels owned by one or more algorithm instances.

DMA Transfer Properties

The unit of each DMA transfer is a block made up of frames and elements. Each DMA transfer is scheduled by issuing a source and destination address for the blocks and the number of elements in each frame. The configured properties of the logical channel at the time of transfer request determine the actual memory that gets copied from source to destination. Each DMA transfer is characterized by the following configurable attributes:

- **transfer type** (xType): 1D-to-1D, 1D-to-2D, 2D-to-1D or 2D-to-2D
- **element size** (elemSize): the number of 8-bit bytes per element \( \in \{1, 2, 4\} \)
- **number of elements** (arg to ACPY2_start): the number of elements per frame, \( 1 \leq \text{number} \leq 65535 \)
- **number of frames** (numFrames): the number of frames in a block, \( 1 \leq \text{number} \leq 65535 \)
- **element index** (srcElementIndex or dstElementIndex): the size of the gap between two consecutive elements within a frame plus the element size in 8-bit bytes. When element index is set to zero (0) element indexing is not used.
- **frame index** (srcFrameIndex or dstFrameIndex): size of the gap in 8-bit bytes between two consecutive frames within a block. Defined for 2D transfers only.

and illustrate the DMA transfers parameters.
**Figure 1-4. Transfer Properties for a 1-D Frame**

**Figure 1-5. Frame Index and 2-D Transfer of N-1 Frames**

[Diagram showing a grid with frame index and frames labeled Frame 0, Frame 1, ..., Frame N-1.]

Element and frame index parameters are shared by both source and destination if hardware does not support setting these independently. The ACPY2_configure function should indicate error status when any configuration settings are not supported by the client implementation.

</tr>
</tbody>
</table>
| Description   | dmaChangeChannels() performs any re-initialization necessary to insure that, if the algorithm's logical DMA channels have been changed by the client, all internal references are updated. The arguments to dmaChangeChannels() are identical to the arguments passed to dmaInit(). In fact, in many cases an algorithm may use the same function defined for dmaInit() to implement dmaChangeChannels(). However, it is important to realize that dmaChangeChannels() is called in real-time whereas dmaInit() is not. The first argument to dmaChangeChannels() is the algorithm's instance handle. The second argument to dmaChangeChannels() is a table of dma records that describe the DMA resource. The handle field in the structure must be initialized to contain a value that indicates the new logical DMA channel. Preconditions The following conditions must be true prior to calling this method; otherwise, its operation is undefined.  
  - handle must be a valid pointer for the algorithm's instance object.  
  - The handle field in the dmaTab[] array must contain a value indicating the new logical DMA channel. Postconditions The following conditions are true immediately after returning from this method.  
  - The instance object is functionally identical to the original instance object. Example
define struct ImageObj {
  IALG_Obj ialg; /* IALG object MUST be first field */
  IDMA2_Handle dmaHandle_0 /* Handle for logical DMA channel 0 */
  IDMA2_Handle dmaHandle_1 /* Handle for logical DMA channel 1 */
  IDMA2_Handle dmaHandle_2 /* Handle for logical DMA channel 2 */
  Bool     grayScale; /* TRUE = grayscale image, FALSE = RGB image */
} ImageObj;

Void dmaChangeChannels(IALG_Handle handle, IDMA2_ChannelRec dmaTab[])
dmachangeChannels - notify algorithm instance that DMA resources have changed

{    ImageObj *img = (ImageObj *)handle;
    img->dmaHandle_0 = dmaTab[0].handle;

    if (!img->grayScale) {
        img->dmaHandle_1 = dmaTab[1].handle;
        img->dmaHandle_2 = dmaTab[2].handle;
    }
}

See Also    dmaInit()
 dmaGetChannelCnt - get number of DMA resources required

Name

dmaGetChannelCnt - get number of DMA resources required

Synopsis

numRecs = dmaGetChannelCnt(Void);

Arguments

Void

Return Value

Int numRecs; /*number of allocation requests for dmaGetChannels*/

Description

dmaGetChannelCnt() returns the maximum number of logical DMA channels requested by each algorithm instance objects for the module. This operation allows the client to allocate sufficient space to call the dmaGetChannels() operation, or fail because of insufficient resources.

Note that dmaGetChannelCnt() can be called before the algorithm instance object is created.

Postconditions

The following conditions are true immediately after returning from this method.

- The return value from dmaGetChannelCnt() is always greater than or equal to zero and always equals or exceeds the value returned by dmaGetChannels().

Example

typedef struct ImageObj {
    IALG_Obj ialg; /* IALG object MUST be first field */
    IDMA2_Handle dmaHandle_0 /* Handle for logical DMA channel 0 */
    IDMA2_Handle dmaHandle_1 /* Handle for logical DMA channel 1 */
    IDMA2_Handle dmaHandle_2 /* Handle for logical DMA channel 2 */
    Bool grayScale; /* TRUE = grayscale image, FALSE = RGB image */
} ImageObj;

Int dmaGetChannelCnt(Void)
{
    return(3) /* Maximum 3 logical channels */
}

dmaGetChannels()
**dmaGetChannels - get algorithm object's dma requirements/holdings**

**Name**

`dmaGetChannels` - get algorithm object's dma requirements/holdings

**Synopsis**

```c
numRecs = dmaGetChannels(IALG_Handle handle, 
IDMA2_ChannelRec dmaTab[]);
```

**Arguments**

- `IALG_Handle handle;`  /* handle to algorithm instance */
- `IDMA2_ChannelRec dmaTab[];`  /* output array of dma records */

**Return Value**

- `Int numRecs;`  /* Number of initialized records in dmaTab[] */

**Description**

dmaGetChannels() returns a table of dma records that describe the algorithm's DMA resources. The `handle` field returned in the `IDMA2_ChannelRec` structure is undefined when this operation is called at algorithm's initialization. All fields in the `IDMA2_ChannelRec` structure are valid if this operation is called after a successful call to the `dmaInit()` operation.

The first argument to `dmaGetChannels()` is the algorithm instance handle.

The second argument to `dmaGetChannels()` is a table of dma records that describe the algorithm's DMA resources.

It is important to notice that the number of logical DMA channels that are being requested might be dependent on the algorithm's interface creation parameters. The algorithm is already initialized with these parameters through `algInit()`.

**Preconditions**

The following conditions must be true prior to calling this method; otherwise, its operation is undefined.

- The number of dma records in the `dmaTab[]` array is equal or less the number returned by `dmaGetChannelCnt()`.
- `handle` must be a valid pointer to the algorithm’s instance object.
- `dmaGetChannels()` can only be called after a successful return from `algInit()`.

**Postconditions**

The following conditions are true immediately after returning from this method.

- Exactly `numRecs` elements of the `dmaTab[]` array are initialized, where `numRecs` is the return value from this operation.
- The `handle` field in the `IDMA2_ChannelRec` structure is valid only if this operation is called after `algInit()`.

**Example**

```c
typedef struct ImageObj { 
    IALG_Obj    ialg;       /* IALG object MUST be first field */
    IDMA2_Handle dmaHandle_0 /* Handle for logical DMA channel 0 */
    IDMA2_Handle dmaHandle_1 /* Handle for logical DMA channel 1 */
};
```
DMA_getChannels - get algorithm object's DMA requirements/holdings

```
IDMA2_Handle dmaHandle_2 /* Handle for logical DMA channel 2 */
Bool                  grayScale; /* TRUE = grayscale image, FALSE = RGB image */

} ImageObj;

typedef struct IMG_Params {
    Int   size;  /* size of this structure */
    Bool  grayScale; /* TRUE = grayscale image, FALSE = RGB image */
} IMG_Params;

const IMG_Params IMG_PARAMS = {   /* default parameters */
    sizeof(IMG_PARAMS),
    TRUE
};

Int algInit(IALG_Handle handle,
IALG_MemRec memTab[], IALG_Handle p, IALG_Params *algParams)
{
    ImageObj *img = (ImageObj *)handle;
    IMG_Params *params = (IMG_Params *)algParams;

    if (params == NULL) {
        params = &IMG_PARAMS;  /* Use interface default parameters */
    }

    /* Initialize the logical DMA channel */
    img->dmaHandle_0 = NULL;
    img->dmaHandle_1 = NULL;
    img->dmaHandle_2 = NULL;
    img->grayScale = params->grayScale;

    return (IALG_EOK);
}

Int dmaGetChannels(IALG_Handle handle, IDMA2_ChannelRec dmaTab[])
{
    ImageObj *img = (ImageObj *)handle;

    /* algInit() is called before this fxn, so the 'grayScale' field */
    /* in the instance object is initialized. */
    return (myDmaTabInit(&img, &dmaTab));
}

static Int myDmaTabInit(ImageObj *img, IDMA2_ChannelRec dmaTab[])
{
    dmaTab[0].handle = img->dmaHandle_0;

    /* If the image is grayscale, require just one logical DMA channel, */
```
/* otherwise request three logical channels; one for each color plane */
if (!img->grayScale) {
    dmaTab[1].handle = img->dmaHandle_1;
    dmaTab[2].handle = img->dmaHandle_2;

    /*
     * Transfers on each logical channel are independent.
     * i.e., each logical channel can be assigned to separate hardware queue.
     */
    dmaTab[0].queueId = 0;
    dmaTab[1].queueId = 1;
    dmaTab[2].queueId = 2;
    return (3);
}
return (1);

**Name**

dmaInit - grant the algorithm DMA resources

**Synopsis**

```
status = dmaInit(IALG_Handle handle, 
                IDMA2_ChannelRec dmaTab[]);
```

**Arguments**

- `IALG_Handle handle;`  /* handle to algorithm instance */
- `IDMA2_ChannelRec dmaTab[];`  /* input array of dma records */

**Return Value**

`Int status;`  /* Status indicating success or failure */

**Description**

dmaInit() performs all initialization of the algorithm instance pointed to by handle necessary for using the DMA resource. After a successful return from dmaInit(), the algorithm instance is ready to use the DMA resource.

The first argument to dmaInit() is the algorithm’s instance handle.

The second argument to dmaInit() is a table of dma records that describe the DMA resources. The handle field in the dmaTab[] array must be initialize by the client of the algorithm to contain a value which indicates a logical channel.

**Preconditions**

The following conditions must be true prior to calling this method; otherwise, its operation is undefined.

- handle must be a valid pointer for the algorithm’s instance object.
- The handle field in the dmaTab[] array must be initialized.
- dmaInit() can only be called after a successful return from algInit().

**Postconditions**

The following conditions are true immediately after returning from this method.

- The algorithm object pointed to by handle has initialized its instance with the DMA resources passed in through dmaTab[].
- The algActivate() operation can be called.

**Example**

typedef struct ImageObj {
    IALG_Obj  ialg;          /* IALG object MUST be first field */
    IDMA2_Handle dmaHandle_0  /* Handle for logical DMA channel 0 */
    IDMA2_Handle dmaHandle_1  /* Handle for logical DMA channel 1 */
    IDMA2_Handle dmaHandle_2  /* Handle for logical DMA channel 2 */
    Bool      grayScale;     /* TRUE = grayscale image, FALSE = RGB image */
} ImageObj;

```
Int dmaInit(IALG_Handle handle, IDMA2_ChannelRec dmaTab[])
```
dmaInit - grant the algorithm DMA resources

{  ImageObj *img = (ImageObj *)handle;
   img->dmaHandle_0 = dmaTab[0].handle;
   /* algInit() is called before this fxn, so the 'grayScale' field */
   /* in the instance object is initialized. */
   if (!img->grayScale) {
      img->dmaHandle_1 = dmaTab[1].handle;
      img->dmaHandle_2 = dmaTab[2].handle;
   }

   /* Additional algorithm initialization related to the DMA resource */
   ........
   ........
   return (IALG_EOK);
}

ACPY2 Runtime APIs

This chapter describes the semantics of the ACPY2 APIs. These APIs can be called by an algorithm that has implemented the IDMA2 interface. A system using an algorithm that has implemented the IDMA2 interface must implement all these APIs.

Algorithms that have already been developed using the deprecated IDMA and ACPY APIs remain eXpressDSP-compliant; however, development of new algorithms should follow the new IDMA2/ACPY2 specification.

</tbody>
</table>
**Synopsis**

dmaDone = ACPY2_complete(IDMA2_Handle handle);

**Arguments**

IDMA2_Handle handle; /* handle to a logical DMA channel */

**Return Value**

Int dmaDone; /* dma completion flag */

**Description**

ACPY2_complete() checks to see if all the data transfers issued on the logical channel pointed to by handle have completed.

The only argument to ACPY2_complete() specifies the logical channel used for the data transfer requested with ACPY2_start() or ACPY2_startAligned().

The framework implementation of ACPY2_complete() must be re-entrant.

**Preconditions**

The following conditions must be true prior to calling this method; otherwise, its operation is undefined.

- handle must be a valid handle to a granted logical DMA channel.

**Postconditions**

The following conditions are true immediately after returning from this method.

- If dmaDone = 0, the data transfer on the logical channel pointed to by handle are still in progress.
- If dmaDone != 0, the data transfer on the logical channel pointed to by handle have completed.

**Examples**

- Check to see if the data transfers the logical channel pointed to be handle have completed.

```c
IDMA2_Handle dmaHandle;
if (ACPY2_complete(dmaHandle) {
    startProcessingData();
} else {
    'do some other work'
}
/* No more processing to do - wait for data transfers to complete */
ACPY2_wait(dmaHandle);
startProcessingData();
```

**See Also**

ACPY2_wait(), ACPY2_StartAligned
Name  

Synopsis  Void ACPY2_configure(IDMA2_Handle handle, IDMA2_Params *params)

Arguments
IDMA2_Handle handle; /* handle to a logical DMA channel */
IDMA2_Params params; /* Channel parameters */

Return Value  Void;

Description  ACPY2_configure() will set up the logical channel pointed to by handle with the values pointed to by params. An algorithm might call this API to prepare for repetitive DMA data transfers with the same configuration. The repetitive data transfers can then be executed faster.

The first argument to ACPY2_configure() specifies the logical channel subject to configuration.

The second argument to ACPY2_configure() points to the specific configuration parameters for the logical channel.

The ACPY2_configure implementation may choose to abort if a particular combination of transfer settings specified in the params argument is not supported in hardware or software. For example, C6x1x EDMA based implementation of ACPY2 may issue a SYS_abort if an algorithm attempts to set values of the frame or element indexes differently for source and destination, or if it requests element indexing for 2D transfers.

The framework implementation of ACPY2_configure() must be re-entrant.

Preconditions  The following conditions must be true prior to calling this method; otherwise, its operation is undefined.

- handle must be a valid pointer to a granted logical DMA channel.
- When element indexing is used, the value in srcElementIndex or dstElementIndex must be a multiple of the element size.
- A value of 0 in srcElementIndex or dstElementIndex disables element indexing.
- The transfer settings specified in the params argument must be supported in hardware or software by the client’s implementation of ACPY2.
- If srcElementIndex is not equal to dstElementIndex then this feature must be supported by the target hardware of the ACPY2 implementation.
- If srcFrameIndex is not equal to dstFrameIndex then this feature must be supported by the target hardware of the ACPY2 implementation.
- params must be non-NULL

Postconditions  The following conditions are true immediately after returning from this method.
The logical channel pointed to by handle is configured according to params.

Frame index settings are ignored in 1D-to-1D transfers.

ACPY2_start() or ACPY2_startAligned() can be called.

Examples

1) Configure the logical channel pointed to by handle for a 1D-to-1D transfer. We assume that the src and dst buffers are aligned on a 32-bit boundary. Note that the numFrames and frame index values will be ignored when xType=IDMA2_1D1D.

```c
IDMA2_Params  params;
IDMA2_Handle  dmaHandle;
params.xType = IDMA2_1D1D;
params.elemSize = IDMA2_ELEM32;
params.numFrames = 0;    /* Not used in 1D1D transfer */
params.srcElemIndex = params.dstElemIndex = 0;

ACPY2_configure(dmaHandle,&params);
```

2) Configure the logical channel pointed to by handle for a 1D-to-2D transfer. We don’t know if the src and dst for the transfer will be aligned, so we set the element size to 8 bits and do byte transfer. Let’s say we want to transfer 8 frames and the “jump” between the end of a frame to the beginning of the next frame is 100 elements.

```c
IDMA2_Params  params;
IDMA2_Handle  dmaHandle;
params.xType = IDMA2_1D2D;
params.elemSize = IDMA2_ELEM8;
params.numFrames = 8;
params.srcElemIndex = params.dstElemIndex = 0;
params.dstFrameIndex = 100;       /* In 8-bit bytes */

ACPY2_configure(dmaHandle,&params);
```

ACPY2_start()
ACPY2_setNumFrames - configure transfer settings for number of frames

Name

ACPY2_setNumFrames - configure transfer settings for number of frames

Synopsis

Void ACPY2_setNumFrames(IDMA2_Handle handle, Uns numFrames)

Arguments

IDMA2_Handle handle;  /* handle to a logical DMA channel */
Uns  numFrames;       /* Channel transfer parameter */

Return Value

Void;

Description

ACPY2_setNumFrames() will quickly configure the number of frames per block setting of the logical channel pointed to by handle with the value passed in numFrames. An algorithm might call this API to prepare for DMA transfers using a different number of frames setting, while retaining all other transfer settings of the current channel’s configuration.

The first argument to ACPY2_configure() specifies the logical channel subject to configuration.

The second argument to ACPY2_configure() holds the number of frames per block configuration parameter for the logical channel.

The framework implementation of ACPY2_setNumFrames() must be re-entrant.

Preconditions

The following conditions must be true prior to calling this method; otherwise, its operation is undefined.

- handle must be a valid pointer to a granted logical DMA channel.
- the channel must be configured with at least one ACPY2_configure call.
- numFrames must be positive for 2D transfers.

Postconditions

The following conditions are true immediately after returning from this method.

- The logical channels number of frames setting is set to numFrames. Old values of all other configuration settings are retained.

Examples

First configure the logical channel pointed to by handle for a 1D-to-2D transfer. We don’t know if the src and dst for the transfer will be aligned, so we must set the element size to 8 bits and do byte transfer. Initial configure call sets the number of frames to 8 and the “jump” between the end of a frame to the beginning of the next frame is 100 elements. The ACPY2_setNumFrames call then changes the number of frames to 10 for subsequent transfers, while keeping all other transfer settings.

```c
IDMA2_Params  params;
IDMA2_Handle  dmaHandle;
params.xType = IDMA2_1D2D;
params.elemSize = IDMA2_ELEM8;
params.numFrames = 8;
params.dstFrameIndex = 100;

ACPY2_configure(dmaHandle,&params);
...
ACPY2_setNumFrames(dmaHandle, 10);
```

ACPY2_configure()
Name

ACPY2_setSrcFrameIndex - configure source frame index settings

Synopsis

Void ACPY2_setSrcFrameIndex(IDMA2_Handle handle, Int frameIndex)

Arguments

IDMA2_Handle handle;  /* handle to a logical DMA channel */
Uns  frameIndex;      /* Channel transfer parameter */

Return Value

Void;

Description

ACPY2_setSrcFrameIndex() will quickly configure the source frame index setting of the logical channel pointed to by handle with the value passed in frameIndex. An algorithm might call this API to prepare for DMA transfers using a different setting for the source frame index, without changing any other transfer settings of the current configuration. For targets where DMA hardware does not support separate source and destination frame indexing the function configures the single frame index shared between the source and the destination.

The first argument to ACPY2_setSrcFrameIndex () specifies the logical channel subject to configuration.

The second argument to ACPY2_setSrcFrameIndex () holds the source frame index value that is used to set the logical channel’s configuration.

The framework implementation of ACPY2_setSrcFrameIndex () must be re-entrant.

Preconditions

The following conditions must be true prior to calling this method; otherwise, its operation is undefined.

- handle must be a valid pointer to a granted logical DMA channel.
- the channel must be configured with at least one ACPY2_configure call.

Postconditions

The following conditions are true immediately after returning from this method.

- The logical channel’s source frame index setting is changed to frameIndex. Old values of all other configuration settings are retained.
- If the target hardware supports a single frame index that is shared by both the source and destination configurations, the shared frame index is configured using the frameIndex arg.

Examples

Configure a logical DMA channel for 2D-to-2D transfers, where each block consists of 18 frames of 16-bits elements that are contiguous, with a gap of 20 bytes between two frames. Then change the source frame index to 10, forcing the subsequent transfers to use 10 byte wide spacing between frames.
ACPY2_setSrcFrameIndex - configure source frame index settings

IDMA2_Params params;
IDMA2_Handle dmaHandle;
params.xType = IDMA2_2D2D;
params.elemSize = IDMA2_ELEM16;
params.numFrames = 18;
params.srcFrameIndex = params.dstFrameIndex = 20;
params.srcElementIndex = params.dstElementIndex = 0;
ACPY2_configure(dmaHandle, &params);

ACPY2_setSrcFrameIndex(dmaHandle, 10);

ACPY2_configure()
ACPY2_setDstFrameIndex - configure destination frame index settings

Name  
ACPY2_setDstFrameIndex - configure destination frame index settings

Synopsis  
Void ACPY2_setDstFrameIndex(IDMA2_Handle handle, Uns frameIndex)

Arguments  
IDMA2_Handle handle; /* handle to a logical DMA channel */
Uns frameIndex; /* Channel transfer parameter */

Return Value  
Void;

Description  
ACPY2_setDstFrameIndex() will quickly configure the destination frame index setting of the logical channel pointed to by handle with the value passed in frameIndex. An algorithm might call this API to prepare for DMA transfers using a different setting for the destination frame index, without changing any other transfer settings of the current configuration. For targets where DMA hardware does not support separate source and destination frame indexing the function configures the single frame index shared between the source and the destination.

The first argument to ACPY2_setDstFrameIndex() specifies the logical channel subject to configuration.

The second argument to ACPY2_setDstFrameIndex() holds the destination frame index value that is used to set the logical channel’s configuration.

The framework implementation of ACPY2_setDstFrameIndex() must be re-entrant.

Preconditions  
The following conditions must be true prior to calling this method; otherwise, its operation is undefined.

- handle must be a valid pointer to a granted logical DMA channel.
- the channel must be configured with at least one ACPY2_configure call.

Postconditions  
The following conditions are true immediately after returning from this method.

- The logical channel’s destination frame index setting is changed to frameIndex. Old values of all other configuration settings are retained.
- If the target hardware supports a single frame index that is shared by both the source and destination configurations, the shared frame index is configured using the frameIndex arg.

Examples  
Configure a logical DMA channel for 2D-to-2D transfers, where each block consists of 18 frames of 16-bits elements that are contiguous, with a gap of 20 bytes between two frames. Then change the destination frame index to 10, forcing the transfer to use 10 bytes wide spacing in destination frames.

IDMA2_Params params;
IDMA2_Handle dmaHandle;
ACPY2_setDstFrameIndex - configure destination frame index settings

```c
params.xType = IDMA2_2D2D;
params.elemSize = IDMA2_ELEM16;
params.numFrames = 18;
params.srcFrameIndex = params.dstFrameIndex = 20;
params.srcElementIndex = params.dstElementIndex = 0;
ACPY2_configure(dmaHandle, &params);
...
ACPY2_setDstFrameIndex (dmaHandle, 10);
```

Void ACPY2_start(IDMA2_Handle handle, IDMA2_AdrPtr src, IDMA2_AdrPtr dst, Int cnt)

Arguments

IDMA2_Handle handle;/* handle to DMA resource*/
IDMA2_AdrPtr src;  /* Source address for data transfer */
IDMA2_AdrPtr dst;  /* Destination addr for data transfer */
Uns cnt;           /* Number of elements in a frame */

Description

ACPY2_start() issues a request for a data transfer. The implementation of ACPY2_start() will copy these values to the appropriate DMA registers and start the data transfer, or put the request on a queue and program the DMA registers when the DMA is available.

The first argument to ACPY2_start() specifies the logical channel used for the data transfer as granted in dmaInit() or as changed with dmaChangeChannels(). Repetitive requests for data transfers will take place in FIFO order.

The second argument to ACPY2_start() specifies the start address for the data transfer.

The third argument to ACPY2_start() specifies the destination address for the data transfer.

The fourth argument to ACPY2_start() indicates the number of elements that will be transferred from src to dst. In the case of a 2D transfer, cnt indicates the number of elements in each frame. The numFrames field in the params structure indicates how many frames of cnt elements that will be transferred. The total number of elements that will be transferred in the 2D case is then (cnt)x(numFrames).

The framework implementation of ACPY2_start() must be re-entrant.

Preconditions

The following conditions must be true prior to calling this method; otherwise, its operation is undefined.

- handle must be a valid pointer to a granted logical DMA channel.
- the logical channel must already be configured through ACPY2_configure().

Postconditions

The following conditions are true immediately after returning from this method.

- the channel configuration settings remains unchanged.
- the data transfer is in progress or in a queue waiting to be started.
- Data transfer will not begin until after completion of all transfer requests that have been previously submitted to the logical channel indicated by the handle or to any other logical channel that shares the same queueId assigned by the same algorithm.

Examples

1) Start a DMA transfer from src to dst of 100 elements on a pre-configured logical channel.

IDMA2_Handle dmaHandle;
IDMA2_AdrPtr src, dst;
ACPY2_start(dmaHandle, src, dst, 100);
ACPY2_start - submit a request for data transfer on a logical DMA channel

2) Start a DMA transfer on a logical channel that currently has a different channel configuration. The transfer is 2D-to-2D, 16-bit elements, 32 contiguous elements in a frame, 18 frames and 20 elements between end of a frame to the start of the next frame.

```c
IDMA2_Params  params;
IDMA2_Handle  dmaHandle;
params.xType = IDMA2_2D2D;
params.elemSize = IDMA2_ELEM16;
params.numFrames = 18;
params.srcElemIndex = params.dstElemIndex = 0;
/* 2 bytes per 16-bit element */
params.srcFrameIndex = params.dstFrameIndex = 20 * 2;
ACPY2_configure(dmaHandle, &params);
ACPY2_start(dmaHandle, src, dst, 32);
```

3) Start three DMA transfers on the same logical channel. The channel is pre-configured, and, all three transfers use the same configuration. The transfer is 2D-to-2D, 8-bit contiguous elements, 16 elements in a frame, 8 frames and 64 elements between end of a frame to the start of the next frame.

```c
IDMA2_Params  params;
IDMA2_Handle  dmaHandle;
params.xType = IDMA2_2D2D;
params.elemSize = IDMA2_ELEM8;
params.numFrames = 8;
params.srcElemIndex = params.dstElemIndex = 0;
params.srcFrameIndex = params.dstFrameIndex = 64
ACPY2_configure(dmaHandle, &params);
ACPY2_start(dmaHandle, src1, dst1, 16);
ACPY2_start(dmaHandle, src2, dst2, 16);
ACPY2_start(dmaHandle, src3, dst3, 16);
```

ACPY2_configure(), ACPY2_complete(), ACPY2_wait(), ACPY2_startAligned()
**ACPY2_wait** - wait all transfers started on this logical DMA channel to finish

**Name**

**ACPY2_wait** - wait all transfers started on this logical DMA channel to finish

**Synopsis**

Void ACPY2_wait(IDMA2_Handle handle);

**Arguments**

IDMA2_Handle handle; /* handle to DMA resource*/

**Return Value**

Void

**Description**

ACPY2_wait() waits for all data transfer issues on the logical channel pointed to by handle to complete. After returning from ACPY2_wait(), all data transfer is guaranteed to be complete.

The only argument to ACPY2_wait() specifies the logical channel used for the data transfer requested with ACPY2_start() or ACPY2_startAligned().

The framework implementation of ACPY2_wait() must be re-entrant.

**Preconditions**

The following conditions must be true prior to calling this method; otherwise, its operation is undefined.

- handle must be a valid handle to a granted logical DMA channel.
- ACPY2_start or ACPY2_startAligned() must have been previously called on the handle.

**Postconditions**

The following conditions are true immediately after returning from this method.

- All data transfer on the logical channel pointed to by handle have completed.

**Examples**

Wait until all DMA data transfers are complete on the logical channel pointed to the handle.

IDMA2_Handle dmaHandle;
ACPY2_wait(dmaHandle);

**See Also**

ACPY2_start(), ACPY2_complete(), ACPY2_startAligned()
ACPY2_getChanObjSize - Return size of the handle for a logical channel

Name

ACPY2_getChanObjSize - Return size of the handle for a logical channel

Synopsis

chanObjSize = ACPY2_getChanObjSize();

Arguments

none

Return Value

Uns chanObjSize; /* dma completion flag */

Description

ACPY2_getChanObjSize() returns the size of the structure used by the underlying ACPY2 library implementation to represent a logical DMA handle where run-time channel state information can be stored.

This function can only be called by the client’s framework and must not be called directly by the algorithm. The client uses the size information obtained by calling ACPY2_getChanObjSize() to allocate the memory needed for the DMA channel handle. The client subsequently must call ACPY2_initChannel() with the handle to initialize the logical channel’s initial state. After its initialization, the handle can be granted to a requesting algorithm.

Preconditions

The following conditions must be true prior to calling this method; otherwise, its operation is undefined.

- none

Postconditions

The following conditions are true immediately after returning from this method.

- chanObjSize returned by the function is always > 0

Examples

Create a logical DMA handle. First inquire size of space needed to store handle, then allocate and initialize the channel associated with the handle.

DMA2_ChannelRec dmaTab[_DMAN_MAXDMARECS];
Int chanObjSize = ACPY2_getChanObjSize();
...
/* Allocate memory for channel handle */
dmaTab[i].handle = (IDMA2_Handle)malloc(chanObjSize);
/* Initialize channel state. Creation of the handle is complete */
ACPY2_initChannel(dmaTab[i].handle, dmaTab[i].queueId);

ACPY2_initChannel()

See Also

ACPY2_initChannel()
Name: ACPY2_initChannel - Return size of the handle for a logical channel

Synopsis: Void ACPY2_initChannel(IDMA2_Handle handle, Int queueId);

Arguments: 
- IDMA2_Handle handle; /* handle to a logical DMA channel */
- Int queueId; /* logical queue identifier */

Return Value: Void

Description: The ACPY2_initChannel() can only be called by the client's framework during the creation of a handle representing a logical DMA channel. It must not be called by the algorithm.

The queueId parameter is used to group several logical DMA channel together to share a single logical queue. The implementation ensures that the logical DMA channels that are initialized with the same value for queueId perform the DMA transfers in a strict first-in first-out (FIFO) fashion corresponding to the order which the DMA transfer requests are submitted to any of the channels.

The client may provide the same queueId information it receives from the algorithm or may apply a framework defined mapping of the algorithm assigned logical queue ids to framework queue ids. This mapping must preserve the algorithm's logical channel grouping requirements.

The client uses the size information obtained by calling ACPY2_getChanObjSize() to allocate the memory needed for the DMA channel handle. After initialization of the logical DMA channel by calling the ACPY2_initChannel() the handle can be granted to a requesting algorithm.

Preconditions: The following conditions must be true prior to calling this method; otherwise, its operation is undefined.

- handle must be non NULL and must point to private memory large enough to hold channel state (as obtained by ACPY2_getChanObjSize call).

Postconditions: The following conditions are true immediately after returning from this method.

- All channels initialized by the same queueId value belong to the same logical queue that strictly orders all DMA transfer requests submitted to any of the channels.
- handle can be used to configure the logical DMA channel settings.

Examples: Create a logical DMA handle. First inquire size of space needed to store handle, then allocate and initialize the channel associated with the handle.

```c
IDMA2_ChannelRec dmaTab[_DMAN_MAXDMARECS];
Int chanObjSize = ACPY2_getChanObjSize();
...
* Allocate memory for channel handle */
dmaTab[i].handle = (IDMA2_Handle)malloc(chanObjSize);
```
ACPY2_initChannel - Return size of the handle for a logical channel

/* Initialize channel state. Creation of the handle is complete */
ACPY2_initChannel(dmaTab[i].handle, dmaTab[i].queueId);
ACPY2_getChanObjSize()

ACPY2_getChanObjSize()
**ACPY2_startAligned** - submit a request for data transfer on a logical DMA channel

**Name**

ACPY2_startAligned

**Synopsis**

Void ACPY2_startAligned(IDMA2_Handle handle, IDMA2_AdrPtr src, IDMA2_AdrPtr dst, Uns cnt)

**Arguments**

- IDMA2_Handle handle; /* handle to DMA resource*/
- IDMA2_AdrPtr src;   /* Source address for data transfer */
- IDMA2_AdrPtr dst;   /* Destination addr for data transfer */
- Uns cnt;            /* Number of elements in a frame */

**Description**

ACPY2_startAligned() issues a request for a data transfer. The implementation of ACPY2_startAligned() will copy these values to the appropriate DMA registers and start the data transfer, or put the request on a queue and program the DMA registers when the DMA is available.

The first argument to ACPY2_startAligned() specifies the logical channel used for the data transfer as granted in dmaInit() or as changed with dmaChangeChannels(). Repetitive requests for data transfers will take place in FIFO order.

The second argument to ACPY2_startAligned() specifies the source address for the data transfer. The caller must ensure that the source address is aligned with respect to the element size.

The third argument to ACPY2_startAligned() specifies the destination address for the data transfer. The caller must ensure that the destination address is aligned with respect to the element size.

The fourth argument to ACPY2_startAligned() indicates the number of elements that will be transferred from src to dst. In the case of a 2D transfer, cnt indicates the number of elements in each frame. The numFrames field in the params structure indicates the number of frames of cnt* elements that will be transferred. The total number of elements that will be transferred in the 2D case is then (cnt)x(numFrames).

The framework implementation of ACPY2_startAligned() must be re-entrant.

**NOTE:** The only operational difference between ACPY2_startAligned() and ACPY2_start() is the additional requirement by ACPY2_startAligned() for its source and destination addresses to be properly aligned with respect to the configured element size. For 32-bit transfers, these addresses must be at least 32-bit aligned. For 16-bit transfers, 16-bit alignment is required. When called with properly aligned addresses, both functions implement an identical behavior. However, in architectures (such as C6000) which permit DMA transfers using 8-bit or 16-bit alignment of src or dst addresses irrespective of the actual transfer element size, the ACPY2_startAligned() function can be optimized to operate more efficiently.

**Preconditions**

The following conditions must be true prior to calling this method; otherwise, its operation is undefined.

- handle must be a valid pointer to a granted logical DMA channel.
- src and dst addresses are aligned with respect to the transfer element size
- the logical channel must already be configured through ACPY2_configure().

Abstract Algorithm Interfaces 2-17
ACPY2_startAligned - submit a request for data transfer on a logical DMA channel

**Postconditions** The following conditions are true immediately after returning from this method.

- the channel configuration settings remains unchanged.
- the data transfer is in progress or in a queue waiting to be started.
- data transfer will not begin until after completion of all transfer requests that have been previously submitted to the logical channel indicated by the handle or to any other logical channel that shares the same queueId assigned by the same algorithm.

**Examples** Start a DMA transfer from src to dst of 100 elements on a preconfigured logical channel.

```c
IDMA2_Handle  dmaHandle;
IDMA2_AdrPtr  src, dst;
ACPY2_startAligned(dmaHandle, src, dst, 100);
```

Start a DMA transfer on a logical channel that currently has a different channel configuration. The transfer is 2D-to-2D, 16-bits elements, 32 contiguous elements in a frame, 18 frames and 20 elements between end of a frame to the start of the next frame. The src and dst addresses are aligned at 16-bit boundaries.

```c
IDMA2_Params  params;
IDMA2_Handle  dmaHandle;
params.xType = IDMA2_2D2D;
params.elemSize = IDMA2_ELEM16;
params.numFrames = 18;
params.srcElemIndex = params.dstElemIndex = 0;
params.srcFrameIndex = params.dstFrameIndex = 20 * 2;
ACPY2_configure(dmaHandle, &params);
ACPY2_startAligned(dmaHandle, src, dst, 32);
```

Start three DMA transfers on the same logical channel. The channel is pre-configured, and, all three transfers use the same configuration. The transfer is 2D-to-2D, 8-bit contiguous elements, 16 elements in a frame, 8 frames and 64 elements between end of a frame to the start of the next frame. Since transfer is in 8-bit element mode, there is no additional alignment requirement on source and destination addresses.

```c
IDMA2_Params  params;
IDMA2_Handle  dmaHandle;
params.xType = IDMA2_2D2D;
params.elemSize = IDMA2_ELEM8;
params.numFrames = 8;
params.srcElemIndex = params.dstElemIndex = 0;
params.srcFrameIndex = params.dstFrameIndex = 64
ACPY2_configure(dmaHandle, &params);
ACPY2_startAligned(dmaHandle, src1, dst1, 16);
ACPY2_startAligned(dmaHandle, src2, dst2, 16);
ACPY2_startAligned(dmaHandle, src3, dst3, 16);
```

Supplementary APIs

This chapter describes supplementary module APIs that are available to the clients of XDAIS algorithms but are not part of the core run-time support. These modules are logically part of an XDAIS framework and are provided to simplify the use and management of eXpressDSP-compliant algorithms. These APIs define a simple XDAIS run-time support library that is provided in the TMS320 DSP Algorithm Standard Developer’s Guide (SPRU424).

☐ ALG – module for the creation of algorithm instance objects

These APIs and any run-time support library provided by the TMS320 DSP Algorithm Standard Developer’s Guide are entirely optional. They are not required in any application that uses XDAIS algorithm components. They are provided to simplify the use of XDAIS components in applications.

The relationship of these interfaces to the abstract interfaces defined in the previous chapter is illustrated by the figure below.

Figure 3-1. Abstract Interfaces and Module Interfaces

Every abstract interface corresponds to an API module that provides a conventional functional interface to any modules that implement the abstract interface. With the exception of the ALG module, these API modules contain little or no code; most operations are type-safe inline functions.
Name: ALG – Algorithm Instance Object Manager

Synopsis: 
#include <alg.h>

Interface:

/*---------------------------*/
/* TYPES AND CONSTANTS */
/*---------------------------*/
typedef IALG_Handle ALG_Handle;

/*---------------------------*/
/* FUNCTIONS */
/*---------------------------*/

ALG_activate();  /* initialize instance’s scratch memory */
ALG_control();   /* send control command to algorithm */
ALG_create();    /* create an algorithm instance object */
ALG_deactivate(); /* save instance’s persistent state */
ALG_delete();    /* delete algorithm instance’s object */
ALG_exit();      /* ALG module finalization */
ALG_init();      /* ALG module initialization */

Description: The ALG module provides a generic (universal) interface used to create, delete, and invoke algorithms on data. The functions provided by this module use the IALG interface functions to dynamically create and delete algorithm objects. Any module that implements the IALG interface can be used by ALG.

The TMS320 DSP Developer’s Kit includes several different implementations of the ALG module each implementing a different memory management policy. Each implementation optimally operates in a specified environment. For example, one implementation never frees memory; it should only be used in applications that never need to delete algorithm objects.
**ALG_activate – initialize scratch memory buffers prior to processing**

**Name**

ALG_activate – initialize scratch memory buffers prior to processing

**Synopsis**

Void ALG_activate(ALG_Handle handle);

**Arguments**

ALG_Handle handle; /* algorithm instance handle */

**Return Value**

Void

**Description**

ALG_activate() initializes any scratch buffers and shared persistent memory using the persistent memory that is part of the algorithm’s instance object. In preemptive environments, ALG_activate() saves all shared data memory used by this instance to a shadow memory so that it can be restored by ALG_deactivate() when this instance is deactivated.

The first (and only) argument to ALG_activate() is an algorithm instance handle. This handle is used by the algorithm to identify the various buffers that must be initialized prior to any processing methods being called.

**See Also**

ALG_deactivate()
**ALG_create** – create an algorithm object

**Synopsis**

```c
handle = ALG_create(IALG_Fxns *fxns, IALG_Params *params);
```

**Arguments**

- `IALG_Fxns   *fxns;    /* pointer to algorithm functions */`
- `IALG_Params  *params; /* pointer to algorithm parameters */`

**Return Value**

`ALG_Handle   handle;  /* non-NULL handle of new object */`

**Description**

`ALG_create()` implements a memory allocation policy and uses this policy to create an instance of the algorithm specified by `fxns`. The `params` parameter is a pointer to an algorithm-specific set of instance parameters that are required by the algorithm to create an instance.

If the return value of `ALG_create()` is `NULL` then it failed; otherwise the handle is non-NULL.

**Example**

```c
#include <alg.h>
#include <encode.h>

Void main()
{
    ENCODE_Params  params;
    ALG_Handle     encoder;

    params = ENCODE_PARAMS; /* initialize to default values */
    params.frameLen = 64;    /* set frame length */

    /* create instance of encoder object */
    encoder = ALG_create(&ENCODE_TI_IALG, (IALG_Params *)&params);

    if (encoder != NULL) {
        /* use encoder to encode data */
        ...
    }

    /* delete encoder object */
    ALG_delete(encoder);
}
```

**See Also**

`ALG_delete()`
ALG_control – send control command to algorithm

Name

Synopsis

ret = ALG_control(ALG_Handle handle,
        ALG_Cmd cmd, ALG_Status *status);

Arguments

ALG_Handle handle;   /* algorithm instance handle */
ALG_Cmd cmd;        /* algorithm specific command */
ALG_Status *status;  /* algorithm specific in/out buffer */

Return Value

Int ret;              /* return status (IALG_EOK, 0) */

Description

ALG_control() sends an algorithm specific command, cmd, and a pointer to an input/output status buffer pointer to an algorithm’s instance object.

The first argument to ALG_control() is an algorithm instance handle. The second two parameters are interpreted in an algorithm-specific manner by the implementation.

The return value of ALG_control() indicates whether the control operation completed successfully. A return value of IALG_EOK indicates that the operation completed successfully; all other return values indicate failure.

Example

#include <alg.h>
#include <encode.h>

Void main()
{
    ALG_Handle encoder;
    ENCODE_Status status;

    /* create instance of encoder object */
    encoder = ...;

    /* tell coder to minimize MIPS */
    status.u.mips = ENCODE_LOW
    ALG_control(encoder, ENCODE_SETMIPS, (ALG_Status *)&status);
    ...
}

### ALG_deactivate – save all persistent data to non-scratch memory

<table>
<thead>
<tr>
<th>Name</th>
<th>ALG_deactivate – save all persistent data to non-scratch memory</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Synopsis</strong></td>
<td>Void ALG_deactivate(ALG_Handle handle);</td>
</tr>
<tr>
<td><strong>Arguments</strong></td>
<td>ALG_Handle handle; /* algorithm instance handle */</td>
</tr>
<tr>
<td><strong>Return Value</strong></td>
<td>Void /* none */</td>
</tr>
</tbody>
</table>

**Description**

ALG_deactivate() saves any persistent information to non-scratch buffers using the persistent memory that is part of the algorithm's instance object. In preemptive environments, ALG_deactivate() also restores any data previously saved to shadow memory by ALG_activate().

The first (and only) argument to ALG_deactivate() is an algorithm instance handle. This handle is used by the algorithm to identify the various buffers that must be saved prior to the next cycle of ALG_activate() and data processing calls.

**See Also**

ALG_activate()
**ALG_delete** – delete an algorithm object

**Name**  
ALG_delete – delete an algorithm object

**Synopsis**  
Void ALG_delete(ALG_Handle handle);

**Arguments**  
ALG_Handle handle; /* algorithm instance handle */

**Return Value**  
Void /* none */

**Description**  
ALG_delete() deletes the dynamically created object referenced by handle, where handle is the return value from a previous call to ALG_create(). If handle is NULL, ALG_delete() simply returns.

**See Also**  
ALG_create()
Name | **ALG_init** — module initialization  
--- | ---  
**Synopsis** | Void ALG_init(VOID);  
**Arguments** | Void /* none */  
**Return Value** | Void /* none */  
**Description** | ALG_init() is called during system startup to perform any run-time initialization necessary for the algorithm module as a whole.  
**See Also** | ALG_create()
Name          ALG_exit – module clean-up

Synopsis      Void ALG_exit(VOID);

Arguments     Void                      /* none */

Return Value  Void                      /* none */

Description   ALG_exit() is called during system shutdown to perform any run-time finalization necessary for the algorithm module as a whole.

See Also      ALG_delete()
This appendix contains the complete source code to two eXpressDSP-compliant algorithm modules; a finite impulse response filter module (FIR) and a filter group module (FIG). Although a digital filter is much too simple an algorithm to encapsulate as an XDAIS component, it illustrates (and hopefully motivates) the concepts presented in the XDAIS specification. The FIR filter example consists of the following files:

1) fir.c, fir.h – FIR utility API module source and interface header
2) ifir.c, ifir.h – abstract FIR interface definition header and parameter defaults
3) fir_ti.c, fir_ti.h – vendor specific implementation and header
4) fir_ti_ext.c – vendor specific extensions to FIR
5) firtest.c, firtest1.c – simple programs using ALG to execute a FIR filter.

For simplicity, all of the IALG interface functions are implemented in a single file and the algorithm is written in C. Figure A-1 illustrates the relationship between the files used in this section.

Figure A-1. FIR Filter Example Implementation
The filter group module, FIG, is an example that illustrates how multiple instances of an algorithm can be grouped together to share common coefficients.

The filter group example consists of the following files.

1) **fig.c, fig.h** – FIG utility API module source and interface header

2) **ifig.h** – abstract FIG interface definition header

3) **fig_ti.c, fig_ti.h** – vendor specific implementation and header

4) **figtest.c** – a simple program using ALG to execute a filter group.

In addition to providing the appropriate run-time interfaces, every eXpressDSP-compliant algorithm must also be accompanied by a characterization of its performance. The required metrics are described in the XDAIS specification and summarized in Appendix A. The spreadsheet below captures the relevant information for the FIR example.

 * ======== fir_ti_ifirvt.c ========
 * This file contains the function table definitions for all
 * interfaces implemented by the FIR_TI module that derive
 * from IALG
 *
 * We place these tables in a separate file for two reasons:
 * 1. We want to allow one to one to replace these tables
 *    with different definitions. For example, one may
 *    want to build a system where the FIR is activated
 *    once and never deactivated, moved, or freed.
 *
 * 2. Eventually there will be a separate "system build"
 *    tool that builds these tables automatically
 *    and if it determines that only one implementation
 *    of an API exists, "short circuits" the vtable by
 *    linking calls directly to the algorithm’s functions.

### Glossary

**Abstract Interface:** An interface defined by a C header whose functions are specified by a structure of function pointers. By convention these interface headers begin with the letter “i” and the interface name begins with “I”. Such an interface is abstract because, in general, many modules in a system implement the same abstract interface; i.e., the interface defines abstract operations supported by many modules.

**Algorithm:** Technically, an algorithm is a sequence of operations, each chosen from a finite set of well-defined operations (for example, computer instructions), that halts in a finite time, and computes a mathematical function. In this specification, however, we allow algorithms to employ heuristics and do not require that they always produce a correct answer.

**API:** Acronym for application programming interface. A specific set of constants, types, variables, and functions used to programmatically interact with a piece of software.

**Client:** The term client denotes any piece of software that uses a function, module, or interface. For example, if the function $a()$ calls the function $b()$, $a()$ is a client of $b()$. Similarly, if an application $App$ uses module $MOD$, $App$ is a client of $MOD$.

**Concrete Interface:** An interface defined by a C header whose functions are implemented by a single module within a system. This is in contrast to an abstract interface where multiple modules in a system can implement the same abstract interface. The header for every module defines a concrete interface.

**Critical Section:** A critical section of code is one in which data that can be accessed by other threads is inconsistent. At a higher level, a critical section is a section of code in which a guarantee you make to other threads about the state of some data may not be true.
If other threads can access these data during a critical section, your program may not behave correctly. This may cause it to crash, lock up, or produce incorrect results.

In order to insure proper system operation, other threads are denied access to inconsistent data during a critical section (usually through the use of locks). Poor system performance could be the result if some of your critical sections are too long.

**Endian:** Refers to which bytes are most significant in multi-byte data types. In big-endian architectures, the leftmost bytes (those with a lower address) are most significant. In little-endian architectures, the rightmost bytes are most significant.

HP, IBM, Motorola 68000, and SPARC systems store multi-byte values in big-endian order, while Intel 80x86, DEC VAX, and DEC Alpha systems store them in little-endian order. Internet standard byte ordering is also big-endian. The TMS320C6000 is bi-endian because it supports both systems.

**Frame:** Algorithms often process multiple samples of data at a time, referred to as a frame. In addition to improving performance, some algorithms require specific minimum frame sizes to operate properly.

**Framework:** Part of an application that is designed to remain invariant while selected software components are added, removed, or modified. Very general frameworks are sometimes described as application-specific operating systems.

**Instance:** The specific data allocated in an application that defines a particular object.

**Interface:** A set of related functions, types, constants, and variables. An interface is often specified with a C header file.

**Interrupt Latency:** The maximum time between when an interrupt occurs and its corresponding interrupt service routine (ISR) starts executing.
Method: A synonym for a function that is part of an interface.

Module: A module is an implementation of one (or more) interfaces. In addition, all modules follow certain design elements that are common to all XDAIS compatible software components. Roughly speaking, a module is a C language implementation of a C++ class.

Multithreading: Multithreading is the management of logically concurrent threads within the same program or system. Most operating systems and modern computer languages also support multithreading.

Preemptive: A property of a scheduler that allows one task to asynchronously interrupt the execution of the currently executing task and switch to another task. The interrupted task is not required to call any scheduler functions to enable the switch.

Reentrant: A property of a program or a part of a program in its executable version, that can be entered repeatedly, or can be entered before previous executions have been completed. Each execution of such a program is independent of all other executions.

Scratch Memory: Memory that can be overwritten without loss; i.e., prior contents need not be saved and restored after each use.

Scratch Register: A register that can be overwritten without loss; i.e., prior contents need not be saved and restored after each use.

Thread: The program state managed by the operating system that defines a logically independent sequence of program instructions. This state may be as small as the program counter (PC) value but often includes a large portion of the CPUs register set.
